

Simulation Object Standard (SOS)

Category: Governance & Enforcement

Subcategory: Simulation Governance

Defines the governance conditions under which the object, system, process, environment, behavior, phenomenon, or other target proposed for simulation is formally identified, bounded, distinguished, versioned, configured, and documented as a governed Simulation Object throughout the simulation lifecycle.

SOS governs the Simulation Object. It establishes the object foundation required before simulation purpose, representation, assumptions, modeling, execution, outputs, evidence use, or lifecycle resimulation can be governed.

A simulation can only meaningfully represent reality when the exact object being simulated is explicitly identified and bounded.

[→ View Standard](#)

Simulation Purpose & Scope Standard (SPSS)

Category: Governance & Enforcement

Subcategory: Simulation Governance

Defines the governance conditions under which the reason for performing a simulation, the questions it must address, the governed portions of the Simulation Object, its exclusions, applicability context, and required depth and precision are formally established before representation begins.

SPSS governs Simulation Purpose & Scope. It prevents a technically successful simulation from silently acquiring a broader purpose, scope, applicability, or interpretive meaning than was actually established.

A simulation cannot legitimately answer a broader question than the question for which it was governed.

[→ View Standard](#)

Reality Representation Standard (RRS)

Category: Governance & Enforcement

Subcategory: Simulation Governance

Defines the governance conditions under which the aspects of reality relevant to a governed Simulation Object, Purpose, Scope, Applicability Context, and required Simulation Depth & Precision are selected, abstracted, represented, resolved, simplified, bounded, and documented within a simulation.

RRS governs Simulation Reality Representation. It keeps the simulated representation explicitly distinguishable from the reality it claims to represent.

A simulation can legitimately represent reality only to the extent that relevant

reality elements are selected, represented, and bounded by known limitations.

[→ View Standard](#)

Simulation Assumption Standard (SAS)

Category: Governance & Enforcement

Subcategory: Simulation Governance

Simulation Assumption Standard (SAS) defines the governance conditions under which assumptions necessary to construct, configure, execute, or interpret a simulation are explicitly identified, justified, bounded, connected to their supporting basis and dependencies, assessed for uncertainty and limitations, and preserved as traceable components of the simulation lifecycle.

A simulation may rely upon assumptions, but no material simulation conclusion should become stronger than the assumptions upon which that conclusion materially depends.

[→ View Standard](#)

Simulation Model & Environment Standard (SMES)

Category: Governance & Enforcement

Subcategory: Simulation Governance

Simulation Model & Environment Standard (SMES) defines the governance conditions under which a simulation model and its simulation environment are constructed, structured, configured, parameterized, bounded, versioned, controlled, and maintained as an identifiable execution context capable of transforming governed Reality Representation and Simulation Assumptions into a controlled simulation structure suitable for subsequent simulation activity.

A simulation becomes structurally governable only when the model and environment through which it operates remain identifiable, bounded, configured, parameterized, versioned, controlled, and traceably connected to the reality representation and assumptions they implement.

[→ View Standard](#)

Simulation Input & Data Standard (SIDS)

Category: Governance & Enforcement

Subcategory: Simulation Governance

Simulation Input & Data Standard (SIDS) defines the governance conditions

under which data, values, signals, measurements, states, distributions, synthetic inputs, and other information may enter a simulation and influence its behavior, requiring material inputs to remain sufficiently identifiable, representative, transformation-governed, temporally appropriate, uncertainty-aware, and traceable to their simulation use.

Information becomes legitimate simulation input only when what it represents, how it was transformed, when it applies, what uncertainty it carries, and where it may influence the simulation remain sufficiently governed.

[→ View Standard](#)

Simulation Scenario Standard (SSS)

Category: Governance & Enforcement
Subcategory: Simulation Governance

Simulation Scenario Standard (SSS) defines the governance conditions under which simulation scenarios are identified, selected, varied, stressed, combined, bounded, and assessed for sufficient coverage so that the simulation examines expected conditions, materially relevant variations, edge cases, failures, uncertainty, stresses, transitions, and plausible alternative conditions capable of affecting simulation outcomes.

A simulation cannot claim meaningful coverage merely because it executes successfully; it must examine the materially relevant conditions capable of changing its behavior or conclusions.

[→ View Standard](#)

Simulation Execution Standard (SES)

Category: Governance & Enforcement
Subcategory: Simulation Governance

Simulation Execution Standard (SES) defines the governance conditions under which a governed simulation is instantiated, executed, controlled, observed, repeated where required, and documented so that the actual execution remains traceable to the Simulation Object, model, environment, scenario, inputs, parameters, configuration, runtime conditions, interventions, deviations, and outputs that formed the execution event. Core Question: How must a simulation be instantiated, executed, observed, repeated, controlled, and documented?

Operational Space: Simulation Execution Governance Operational Scope:
Instantiation · Execution Control · Observation · Repetition · Execution
Documentation Governance Flow Position: 8 of 12 — Simulation Scenario →
Simulation Execution → Simulation Output Governance Origin ID: OOF-SIMULOS-SES
Canonical Definition: Simulation Execution Standard (SES) defines the governance conditions under which a governed simulation is instantiated, executed, controlled, observed, repeated where required, and documented so

that the actual execution remains traceable to the Simulation Object, model, environment, scenario, inputs, parameters, configuration, runtime conditions, interventions, deviations, and outputs that formed the execution event. Core Question: How must a simulation be instantiated, executed, observed, repeated, controlled, and documented? Foundational Principle: A simulation result cannot be fully understood from its output alone; it must remain connected to the execution conditions and execution history that produced it.

[→ View Standard](#)

Simulation Output Governance Standard (SOGS)

Category: Governance & Enforcement
Subcategory: Simulation Governance

Simulation Output Governance Standard (SOGS) defines the governance conditions under which outputs produced by Simulation Execution are formally identified, classified, bounded, interpreted, documented, and connected to the execution basis that produced them, ensuring that what the simulation directly produced remains distinguishable from derived results, subsequent inference, material limitations, and claims extending beyond the simulation itself.

A Simulation Output becomes legitimately governable only when its origin, classification, interpretive boundary, material limitations, and relationship to the Simulation Execution that produced it remain explicit and traceable.

[→ View Standard](#)

Simulation-to-Reality Correlation Standard (SRCS)

Category: Governance & Enforcement
Subcategory: Simulation Governance

Simulation-to-Reality Correlation Standard (SRCS) defines the governance conditions under which simulated conditions, behaviors, states, events, relationships, and outputs are systematically compared with corresponding Operational Reality to determine where meaningful correlation exists, where material deviation occurs, how Reality Alignment varies across conditions, and with what uncertainty and limitations any resulting correlation claim may legitimately be made. Core Question: To what extent do simulated behavior, conditions, and outputs correspond to the reality they claim to represent? Architectural Boundary: ORA™ governs Operational Reality. SIMULOS® SRCS governs the correlation relationship between Simulation and Operational Reality. VALIDOS® governs what validation conclusion that correlation may subsequently support.

Operational Space: Simulation-to-Reality Correlation Governance Operational Scope: Comparison · Correlation Criteria · Deviation · Reality Alignment · Correlation Uncertainty Governance Flow Position: 10 of 12 — Simulation Output Governance → Simulation-to-Reality Correlation → Downstream Simulation

Lifecycle Governance Origin ID: OOF-SIMULOS-SRCS Canonical Definition: Simulation-to-Reality Correlation Standard (SRCS) defines the governance conditions under which simulated conditions, behaviors, states, events, relationships, and outputs are systematically compared with corresponding Operational Reality to determine where meaningful correlation exists, where material deviation occurs, how Reality Alignment varies across conditions, and with what uncertainty and limitations any resulting correlation claim may legitimately be made. **Core Question:** To what extent do simulated behavior, conditions, and outputs correspond to the reality they claim to represent? **Architectural Boundary:** ORA™ governs Operational Reality. SIMULOS® SRCS governs the correlation relationship between Simulation and Operational Reality. VALIDOS® governs what validation conclusion that correlation may subsequently support. **Foundational Principle:** Simulation similarity is not reality equivalence.

[→ View Standard](#)

Simulation Evidence & Reliance Boundary Standard (SERBS)

Category: Governance & Enforcement
Subcategory: Simulation Governance

Simulation Evidence & Reliance Boundary Standard governs what simulation-derived information may legitimately become evidence, what evidential meaning and weight that evidence may carry, how far reliance upon it may extend, which uses must remain limited, and how simulation evidence interfaces with broader validation governance.

Simulation-derived evidence must not be relied upon beyond the conditions, assumptions, scenarios, correlations, uncertainties, and limitations that establish its legitimate evidential meaning.

[→ View Standard](#)

Simulation Lifecycle & Resimulation Standard (SLRS)

Category: Governance & Enforcement
Subcategory: Simulation Governance

Simulation Lifecycle & Resimulation Standard governs how simulation relevance is monitored over time, how material drift between the governed simulation basis and changing reality is recognized, and when change requires resimulation, update, replacement, or retirement.

A simulation remains governably relevant only while the conditions that

support its meaning remain materially applicable; when those conditions change, continued reliance requires governed reassessment.

[→ View Standard](#)

Validation Object Standard (VOBS)

Architecture Family: VALIDOS® — Validation Governance Architecture

Category: AI & Interpretation

Subcategory: Validation Governance

Validation Object Standard (VOBS) defines the governance conditions under which an entity, claim, output, decision, model, system, process, dataset, state, or other subject requiring validation is formally identified, bounded, versioned, relationally situated, and established as a validation-ready governed object.

[→ View Standard](#)

Validation Purpose & Scope Standard (VPSS)

Architecture Family: VALIDOS® — Validation Governance Architecture

Category: AI & Interpretation

Subcategory: Validation Governance

Validation Purpose & Scope Standard (VPSS) defines the governance conditions under which the purpose, boundaries, depth, applicability, limitations, and intended use of validation are formally established before validation criteria, methodology, evidence assessment, execution, determination, state, or reliance are governed.

[→ View Standard](#)

Validation Criteria Standard (VCRS)

Architecture Family: VALIDOS® — Validation Governance Architecture

Category: AI & Interpretation

Subcategory: Validation Governance

Validation Criteria Standard (VCRS) defines the governance conditions under which the criteria, requirements, thresholds, acceptance conditions, rejection conditions, evaluation references, and decision boundaries used to determine validity are formally established, justified, structured, maintained, and controlled before validation methodology and execution are applied.

[→ View Standard](#)

Validation Method Standard (VMTS)

Architecture Family: VALIDOS® — Validation Governance Architecture

Category: AI & Interpretation

Subcategory: Validation Governance

Validation Method Standard (VMTS) defines the governance conditions under which validation methods are identified, selected, justified, configured, combined, controlled, and maintained so that established Validation Criteria can be examined through methods appropriate to the Validation Object, Validation Purpose, Validation Scope, required Validation Depth, applicable conditions, and intended Validation Determination.

[→ View Standard](#)

Validation Evidence Fitness Standard (VEFS)

Architecture Family: VALIDOS® — Validation Governance Architecture

Category: AI & Interpretation

Subcategory: Validation Governance

Validation Evidence Fitness Standard (VEFS) defines the governance conditions under which evidence intended to support validation is identified, qualified, assessed, bounded, and determined to be sufficiently relevant, applicable, complete, representative, timely, precise, and methodologically usable for the specific Validation Object, Validation Criteria, Validation Method, Validation Purpose, Validation Scope, and required Validation Depth.

[→ View Standard](#)

Validation Source Reliability Standard (VSRS)

Architecture Family: VALIDOS® — Validation Governance Architecture

Category: AI & Interpretation

Subcategory: Validation Governance

Validation Source Reliability Standard (VSRS) defines the governance conditions under which sources providing, generating, transmitting, recording, transforming, interpreting, or maintaining Validation Evidence are identified, attributable, provenance-aware, independence-assessed, integrity-aware, competence-aware, conflict-aware, and sufficiently reliable for their assigned role within a governed validation process.

[→ View Standard](#)

Validation Execution Standard (VEXS)

Architecture Family: VALIDOS® — Validation Governance Architecture

Category: AI & Interpretation

Subcategory: Validation Governance

Validation Execution Standard (VEXS) defines the governance conditions under which an approved validation method is instantiated, performed, controlled, observed, documented, monitored, and completed against the established Validation Object, Validation Purpose, Validation Scope, Validation Criteria, qualified evidence basis, and reliability-qualified source structure.

[→ View Standard](#)

Validation Determination Standard (VDTS)

Architecture Family: VALIDOS® — Validation Governance Architecture

Category: AI & Interpretation

Subcategory: Validation Governance

Validation Determination Standard (VDTS) defines the governance conditions under which the complete governed validation record is evaluated, integrated, interpreted, bounded, and transformed into a formal Validation Determination establishing what the executed validation legitimately demonstrates about the Validation Object relative to the applicable Validation Criteria, thresholds, conditions, evidence, methodological limitations, execution conformity, uncertainty, conflicts, and approved Validation Scope.

[→ View Standard](#)

Validation State Governance Standard (VSGS)

Architecture Family: VALIDOS® — Validation Governance Architecture

Category: AI & Interpretation

Subcategory: Validation Governance

Validation State Governance Standard (VSGS) defines the governance conditions under which Validation Objects are assigned, maintained, transitioned, restricted, suspended, invalidated, expired, superseded, and reclassified across formal Validation States based upon applicable Validation Determinations, object identity, object version, scope, conditions, lifecycle events, material change, temporal validity, unresolved limitations, and revalidation

requirements.

[→ View Standard](#)

Validation Reliance & Revalidation Standard (VRRS)

Architecture Family: VALIDOS® — Validation Governance Architecture

Category: AI & Interpretation

Subcategory: Validation Governance

Validation Reliance & Revalidation Standard (VRRS) defines the governance conditions under which a person, organization, institution, system, AI, autonomous agent, process, or other governed actor may rely upon a current Validation State for a defined purpose, scope, decision, action, or operational use, and establishes when changes in that Validation State, its applicability, conditions, evidence, object, environment, risk, or lifecycle require reliance to be restricted, suspended, withdrawn, or renewed through governed revalidation.

[→ View Standard](#)

Audit Observation Standard (AOS)

Category: Governance & Enforcement

Subcategory: Audit & Evidence Governance

Defines the structural conditions under which operational reality becomes observable, attributable, context-aware, boundary-defined, and valid for trustworthy evidence formation throughout the complete lifecycle of any governed entity.

AOS governs audit observation.

No trustworthy audit begins without trustworthy observation.

[→ View Standard](#)

Evidence Formation Standard (EFS)

Category: Governance & Enforcement

Subcategory: Audit & Evidence Governance

Defines the structural conditions under which governed audit observations become structured, trustworthy, attributable, and governable evidence throughout the complete lifecycle of any governed entity.

EFS governs evidence formation.

Trustworthy evidence begins with governed evidence formation.

[→ View Standard](#)

Evidence Integrity Standard (EIS)

Category: Governance & Enforcement
Subcategory: Audit & Evidence Governance

Defines the structural conditions under which governed evidence remains authentic, complete, trustworthy, protected, and continuously preservable throughout the complete lifecycle of any governed entity.

Evidence Integrity Standard governs evidence integrity. It establishes the methodological foundation for preserving the trustworthiness of evidence after evidence formation and before evidence correlation begins.

Trustworthy evidence requires continuously preserved integrity.

[→ View Standard](#)

Evidence Correlation Standard (ECS)

Category: Governance & Enforcement
Subcategory: Audit & Evidence Governance

Defines the structural conditions under which independently governed evidence is connected, contextualized, sequenced, and correlated to reconstruct operational reality while preserving evidence integrity.

Evidence Correlation Standard governs evidence correlation.

Evidence becomes operationally meaningful when its relationships are governed.

[→ View Standard](#)

Evidence Verification Standard (EVS)

Category: Governance & Enforcement
Subcategory: Audit & Evidence Governance

Defines the structural conditions under which correlated evidence is objectively verified for accuracy, reliability, completeness, consistency, authenticity, and sufficiency before it is accepted for audit execution or governance decision-making.

Evidence Verification Standard governs evidence verification.

Evidence becomes trustworthy for audit only after objective verification.

[→ View Standard](#)

Audit Execution Standard (AES)

Category: Governance & Enforcement
Subcategory: Audit & Evidence Governance

Defines the structural conditions under which governed audits are executed objectively, consistently, transparently, and repeatably using objectively verified evidence.

Audit Execution Standard governs audit execution.

Reliable audit outcomes require governed audit execution.

[→ View Standard](#)

Audit Findings Standard (AFS)

Category: Governance & Enforcement
Subcategory: Audit & Evidence Governance

Defines the structural conditions under which audit findings are objectively identified, documented, classified, validated, and governed using verified evidence and governed audit execution.

Audit Findings Standard governs audit findings.

Every audit finding must be supported by verified evidence.

[→ View Standard](#)

Audit Response Standard (ARS)

Category: Governance & Enforcement
Subcategory: Audit & Evidence Governance

Defines the structural conditions under which validated audit findings are evaluated, planned, approved, implemented, monitored, verified, and governed through accountable organizational responses.

Audit Response Standard governs audit response.

Every validated audit finding should lead to a governed and accountable response.

[→ View Standard](#)

Audit Preservation Standard (APS)

Category: Governance & Enforcement

Subcategory: Audit & Evidence Governance

Defines the structural conditions under which audit evidence, execution history, findings, responses, decisions, and governance records remain preserved, accessible, trustworthy, and reconstructable throughout their complete lifecycle.

Audit Preservation Standard governs audit preservation.

Trustworthy audits require trustworthy preservation.

[→ View Standard](#)

Audit Assurance Standard (AAS)

Category: Governance & Enforcement

Subcategory: Audit & Evidence Governance

Defines the structural conditions under which the complete audit lifecycle remains continuously trustworthy, objective, independent, complete, and independently verifiable.

Audit Assurance Standard governs audit assurance. It establishes the methodological foundation for independently assuring the quality, integrity, completeness, and trustworthiness of the entire audit process.

A trustworthy audit requires trustworthy assurance.

[→ View Standard](#)

Classification Foundation Standard

Architecture Family: CLA™ — Classification Architecture

Category: AI & Interpretation

Subcategory: Classification Governance

Defines the structural conditions under which classification establishes a consistent, objective, governable, and methodologically valid foundation before any classification activity begins.

Classification Foundation Standard governs classification foundation.

It establishes the methodological foundation required to ensure that every classification remains coherent, reproducible, explainable, comparable, and governance-valid throughout its complete lifecycle.

Trustworthy classification begins with a trustworthy foundation.

[→ View Standard](#)

Classification Scope Standard (CSS)

Architecture Family: CLA™ — Classification Architecture

Category: AI & Interpretation

Subcategory: Classification Governance

Defines the structural conditions under which the scope, boundaries, applicability, coverage, and limitations of classification remain objectively defined, governed, and methodologically valid.

Classification Scope Standard governs **classification scope**.

It establishes the methodological foundation for defining where classification applies, what it includes, what it excludes, and the authorized boundaries within which classification may legitimately operate.

Trustworthy classification requires a clearly governed scope.

[→ View Standard](#)

Classification Context Standard (CCXS)

Architecture Family: CLA® — Classification Architecture

Category: AI & Interpretation

Subcategory: Classification Governance

Defines the structural conditions under which classification remains contextually correct, operationally relevant, consistent, and independently verifiable across different environments and decision conditions.

Classification Context Standard governs **classification context**.

It establishes the methodological foundation for identifying, evaluating, validating, and governing the contextual factors that influence classification decisions throughout their complete lifecycle.

A correct classification is only correct within its governed context.

[→ View Standard](#)

Classification Assignment Standard (CAS)

Architecture Family: CLA® — Classification Architecture

Category: AI & Interpretation

Subcategory: Classification Governance

Defines the structural conditions under which classifications are assigned accurately, consistently, transparently, and independently verifiably using approved scope, established criteria, and validated context.

Classification Assignment Standard governs **classification assignment**.

It establishes the methodological foundation for assigning, documenting, validating, and governing classification decisions throughout their complete lifecycle.

A classification becomes trustworthy only when its assignment is governed.

[→ View Standard](#)

Classification Validation Standard (CVS)

Architecture Family: CLA® — Classification Architecture

Category: AI & Interpretation

Subcategory: Classification Governance

Defines the structural conditions under which assigned classifications remain accurate, justified, consistent, governance-compliant, and independently verifiable.

Classification Validation Standard governs **classification validation**.

It establishes the methodological foundation for independently verifying, evaluating, confirming, and governing classification decisions throughout their complete lifecycle.

A classification becomes trustworthy only after independent validation.

[→ View Standard](#)

Classification Lifecycle Standard (CLS)

Architecture Family: CLA™ — Classification Architecture

Category: Governance & Classification

Subcategory: Classification Governance

Defines the structural conditions under which classifications remain governed, current, controlled, traceable, and operationally relevant throughout their complete lifecycle.

Classification Lifecycle Standard governs classification lifecycle.

It establishes the methodological foundation for activating, maintaining, updating, versioning, monitoring, and retiring classifications while preserving their integrity and operational reliability over time.

A trustworthy classification must remain governed throughout its entire lifecycle.

[→ View Standard](#)

Classification Registry Standard (CRS)

Architecture Family: CLA™ — Classification Architecture

Category: Governance & Classification

Subcategory: Classification Governance

Defines the structural conditions under which classifications remain uniquely identifiable, centrally registered, discoverable, traceable, and continuously governed throughout their complete lifecycle.

Classification Registry Standard governs **classification registry**.

It establishes the methodological foundation for registering, uniquely identifying, organizing, maintaining, discovering, and governing classifications within an authoritative registry.

A trustworthy classification requires a trustworthy registry.

[→ View Standard](#)

Classification Interoperability Standard (CIS)

Architecture Family: CLA™ — Classification Architecture

Category: Governance & Classification

Subcategory: Classification Governance

Defines the structural conditions under which classifications remain compatible, consistently interpreted, transferable, and operationally interoperable across systems, organizations, platforms, and governance environments.

Classification Interoperability Standard governs **classification interoperability**.

It establishes the methodological foundation for classification compatibility, mapping, translation, synchronization, consistency validation, and trusted cross-domain classification exchange.

A classification creates value only when it can be consistently understood wherever it is used.

[→ View Standard](#)

Classification Intelligence Standard (CIS)

Architecture Family: CLA™ — Classification Architecture

Category: Governance & Classification

Subcategory: Classification Governance

Defines the structural conditions under which classifications generate trustworthy, explainable, consistent, and operationally reliable intelligence throughout their complete lifecycle.

Classification Intelligence Standard governs **classification intelligence**.

It establishes the methodological foundation for analytical interpretation, reasoning, operational insight generation, decision support, intelligence validation, and continuous intelligence governance.

A governed classification should generate governed intelligence.

[→ View Standard](#)

Classification Assurance Standard (CAS)

Architecture Family: CLA™ — Classification Architecture

Category: Governance & Classification

Subcategory: Classification Governance

Defines the structural conditions under which the complete classification lifecycle remains continuously trustworthy, complete, objective, governed, and independently verifiable.

Classification Assurance Standard governs **classification assurance**.

It establishes the methodological foundation for independently assuring the quality, integrity, completeness, interoperability, intelligence, and trustworthiness of the complete classification lifecycle.

A trustworthy classification requires trustworthy assurance.

[→ View Standard](#)

Integrity Definition Standard (INDS)

Category: Governance & Enforcement

Subcategory: Integrity Governance

Defines the structural conditions under which the meaning of integrity is

formally established for any governed entity before integrity can be measured, governed, or independently verified.

INDS governs integrity definition. The standard establishes the canonical governance conditions required to determine what integrity means before integrity can be measured, evaluated, protected, restored, or assured.

Integrity cannot be governed until integrity has been defined.

INDS establishes that foundation.

[→ View Standard](#)

Structural Integrity Standard (STIS)

Category: Governance & Enforcement

Subcategory: Integrity Governance

Defines the structural conditions required for a governed entity to preserve integrity by governing its organization, components, relationships, dependencies, and structural coherence throughout its complete lifecycle.

STIS governs the structure required to preserve integrity under normal operation, change, and evolution.

Structure determines whether integrity can endure.

STIS governs that structure.

[→ View Standard](#)

Integrity Condition Standard (ICS)

Category: Governance & Enforcement

Subcategory: Integrity Governance

Defines the mandatory governance conditions that must remain continuously satisfied for a governed entity to preserve integrity by governing its rules, constraints, dependencies, and operational requirements throughout its complete lifecycle.

Governed Space:
Integrity Conditions

Integrity exists only while its governing conditions remain true.

[→ View Standard](#)

Integrity Measurement Standard (IMS)

Category: Governance & Enforcement

Subcategory: Integrity Governance

Defines the governance conditions required to objectively measure integrity by establishing metrics, indicators, thresholds, evaluation models, and scoring mechanisms throughout the complete lifecycle of a governed entity.

Governed Space:

Integrity Measurement

Integrity can only be governed objectively when it can be measured consistently.

[→ View Standard](#)

Integrity State Standard (ISS)

Category: Governance & Enforcement

Subcategory: Integrity Governance

Defines the governance conditions required to determine, classify, and maintain the current operational state of integrity by establishing standardized integrity states, state transition rules, and governance criteria throughout the complete lifecycle of a governed entity.

Governed Space:

Integrity State

Integrity is governed not only by what is measured, but by the operational state those measurements collectively represent.

[→ View Standard](#)

Integrity Deviation Standard (IDS)

Category: Governance & Enforcement

Subcategory: Integrity Governance

Defines the governance conditions required to detect, classify, evaluate, and manage deviations from an approved integrity state by establishing deviation criteria, severity levels, evaluation methods, and governance rules throughout the complete lifecycle of a governed entity.

Governed Space:

Integrity Deviation

Integrity breaches are rarely the beginning of failure. Most failures begin as governed deviations that remain undetected or unmanaged.

[→ View Standard](#)

Integrity Breach Standard (IBS)

Category: Governance & Enforcement

Subcategory: Integrity Governance

Defines the governance conditions required to identify, verify, classify, assess, and govern integrity breaches by establishing breach determination criteria, evidence requirements, severity models, and governance rules throughout the complete lifecycle of a governed entity.

Governed Space:

Integrity Breach

An integrity breach is not the existence of a problem—it is the governed determination that integrity has been materially compromised according to approved governance conditions.

Auditability Integrity Standard (AUDIS)

Category: Governance & Enforcement

Subcategory: Identity Governance

Defines the structural conditions under which every governance aspect of a governed identity remains independently reviewable, verifiable, evidence-supported, traceable, and continuously governable throughout the complete identity lifecycle.

AUDIS governs **identity auditability**.

Trustworthy identity governance requires trustworthy auditability.

[→ View Standard](#)

Continuity Integrity Standard (CIS)

Category: Governance & Enforcement

Subcategory: Identity Governance

Defines the structural conditions under which a governed identity preserves its continuity, legitimacy, traceability, provenance, governance relationships, and continuous governability throughout the complete identity lifecycle despite legitimate lifecycle changes.

CIS governs **continuity integrity**.

Trustworthy identity governance requires trustworthy continuity.

[→ View Standard](#)

Transfer Integrity Standard (TIS)

Category: Governance & Enforcement

Subcategory: Identity Governance

Defines the structural conditions under which a governed identity and its associated governance relationships may be transferred while preserving legitimacy, continuity, traceability, accountability, and continuous governability throughout the complete identity lifecycle.

TIS governs **transfer integrity**.

Trustworthy identity governance requires trustworthy transfer.

[→ View Standard](#)

Provenance Integrity Standard (PRIS)

Category: Governance & Enforcement

Subcategory: Identity Governance

Defines the structural conditions under which the provenance of a governed identity remains authentic, complete, traceable, verifiable, evidence-supported, and continuously governable throughout the complete identity lifecycle.

PRIS governs **provenance integrity**.

Trustworthy identity governance requires trustworthy provenance.

[→ View Standard](#)

Responsibility Integrity Standard (RIS)

Category: Governance & Enforcement

Subcategory: Identity Governance

Defines the structural conditions under which responsibility associated with a governed identity remains legitimate, attributable, verifiable, continuous, and continuously governable throughout the complete identity lifecycle.

RIS governs **responsibility integrity**.

Trustworthy identity governance requires trustworthy responsibility.

[→ View Standard](#)

Permission Integrity Standard (PIS)

Category: Governance & Enforcement

Subcategory: Identity Governance

Defines the structural conditions under which permissions associated with a governed identity remain legitimate, attributable, verifiable, enforceable, revocable, and continuously governable throughout the complete identity lifecycle.

PIS governs **permission integrity**.

Trustworthy identity governance requires trustworthy permissions.

[→ View Standard](#)

Authority Integrity Standard (AIS)

Category: Governance & Enforcement

Subcategory: Identity Governance

Defines the structural conditions under which authority over a governed identity remains legitimate, attributable, verifiable, delegated, and continuously governable throughout the complete identity lifecycle.

AIS governs **identity authority**.

Trustworthy authority enables trustworthy identity governance.

[→ View Standard](#)

Ownership Integrity Standard (OWIS)

Category: Governance & Enforcement

Subcategory: Identity Governance

Defines the structural conditions under which ownership of a governed identity remains legitimate, attributable, verifiable, and continuously governable.

OWIS governs **ownership integrity**.

Trustworthy ownership begins with trustworthy identity.

[→ View Standard](#)

Identity Integrity Standard (IIS)

Category: Governance & Enforcement

Subcategory: Identity Governance

Defines the structural conditions under which governed identity remains unique, authentic, verifiable, distinguishable, and continuously governable.

IIS governs **identity integrity**.

Trustworthy governance requires trustworthy identity.

[→ View Standard](#)

Origin Integrity Standard (OIS)

Category: Governance & Enforcement Subcategory: Identity Governance

Defines the structural conditions under which the origin of a governed identity remains authentic, verifiable, attributable, traceable, and continuously governable throughout its complete lifecycle.

OIS governs **origin integrity**.

Trustworthy identity begins with trustworthy origin.

[→ View Standard](#)

Behavioral Integrity Standard (BIS)

Category: AI Governance

Subcategory: AI Behavioral Governance

Defines the structural conditions under which AI behavior remains legitimate, consistent, predictable, explainable, governable, observable, traceable, and operationally trustworthy throughout the complete behavioral lifecycle.

BIS governs AI behavioral integrity.

The standard establishes the conditions required to ensure that AI systems behave consistently with approved objectives, governance policies, operational constraints, and legitimate behavioral expectations throughout operational reality.

AI behavior may evolve.

AI behavior must not lose its integrity.

Behavior is the visible expression of AI.

Behavioral Integrity therefore becomes the foundational condition of trustworthy AI Governance Architecture (AIG®).

[→ View Standard](#)

Behavioral Boundary Standard (BBS)

Category: AI Governance

Subcategory: AI Behavioral Governance

Defines the structural conditions under which AI behavior remains confined within authorized behavioral boundaries, operational limits, governance constraints, delegated permissions, and approved behavioral domains throughout the complete behavioral lifecycle.

BBS governs AI behavioral boundaries.

The standard establishes the conditions required to ensure that AI systems operate only within approved behavioral limits, preventing unauthorized behavioral expansion, boundary violations, uncontrolled autonomy, or governance-invalid behavior.

AI behavior requires freedom to operate.

AI behavior also requires boundaries.

Behavior without boundaries cannot remain governable.

Behavioral Boundaries therefore become the second foundational condition of trustworthy AI Governance Architecture (AIG®).

[→ View Standard](#)

Behavioral Escalation Standard (BES)

Category: AI Governance

Subcategory: AI Behavioral Governance

Defines the structural conditions under which AI behavior triggers appropriate escalation, intervention, notification, authority transfer, operational restriction, or human oversight when predefined behavioral conditions, governance thresholds, or operational risks are exceeded throughout the complete behavioral lifecycle.

BES governs AI behavioral escalation.

The standard establishes the conditions required to ensure that AI systems never continue autonomous behavior beyond approved governance thresholds without appropriate escalation to higher authority or alternative governance mechanisms.

AI cannot resolve every situation autonomously.

AI must know when to escalate.

Trustworthy AI knows not only how to act, but also when to ask for help.

Behavioral Escalation therefore becomes the third foundational condition of trustworthy AI Governance Architecture (AIG®).

[→ View Standard](#)

Behavioral Auditability Standard (BAS)

Category: AI Governance

Subcategory: AI Behavioral Governance

Defines the structural conditions under which AI behavior remains observable, reconstructable, verifiable, attributable, explainable, traceable, and independently auditable throughout the complete behavioral lifecycle.

BAS governs AI behavioral auditability.

The standard establishes the conditions required to ensure that every significant AI behavioral activity can be independently reconstructed, reviewed, verified, and audited using trustworthy governance evidence.

AI behavior should never become a black box.

AI behavior must remain auditable.

Behavior that cannot be audited cannot be fully governed.

Behavioral Auditability therefore becomes the fourth foundational condition of trustworthy AI Governance Architecture (AIG®).

[→ View Standard](#)

Behavioral Evidence Standard (BVES)

Category: Governance & Enforcement

Subcategory: AI Behavioral Evidence Governance

Defines the structural conditions under which AI behavior produces complete, reliable, authentic, attributable, governance-valid, and decision-supporting evidence throughout the complete behavioral lifecycle.

BVES governs AI behavioral evidence.

The standard establishes the conditions required to ensure that every significant AI behavioral activity generates trustworthy evidence suitable for governance, accountability, compliance, investigation, regulatory oversight, and organizational decision-making.

AI behavior creates actions.

Actions create evidence.

Trustworthy governance depends on trustworthy evidence.

Behavioral Evidence transforms AI activity into governance knowledge that remains valuable long after the behavior itself has ended.

[→ View Standard](#)

Behavioral Trust Standard (BTS)

Category: Governance & Enforcement

Subcategory: AI Behavioral Trust Governance

Defines the structural conditions under which AI behavior becomes, remains, loses, and restores trust through consistent governance, observable integrity, accountable operation, reliable evidence, and verifiable behavioral performance throughout the complete behavioral lifecycle.

BTS governs AI behavioral trust.

The standard establishes the conditions required to ensure that trust becomes a measurable governance outcome rather than an assumption, expectation, or marketing claim.

Trust cannot be demanded.

Trust cannot be programmed.

Trust must be earned through behavior.

Behavioral Trust enables organizations to rely on AI with confidence because confidence is built on governed behavior, not technological promises.

[→ View Standard](#)

Behavioral Correction Standard (BCS)

Category: Governance & Enforcement

Subcategory: AI Behavioral Correction Governance

Defines the structural conditions under which AI behavior can be identified, corrected, validated, monitored, and continuously improved through accountable, transparent, evidence-based, and governance-directed correction throughout the complete behavioral lifecycle.

BCS governs AI behavioral correction.

The standard establishes the conditions required to ensure that behavioral correction remains governed, justified, verifiable, and aligned with organizational governance objectives rather than becoming reactive, arbitrary, or uncontrolled.

AI behavior should not remain static.

AI behavior should improve responsibly.

Behavioral correction ensures that improvement remains governed rather than accidental.

[→ View Standard](#)

Behavioral Continuity Standard (BCNS)

Category: Governance & Enforcement

Subcategory: AI Behavioral Continuity Governance

Defines the structural conditions under which AI behavior remains consistent, stable, governable, recoverable, and operationally reliable despite system evolution, organizational change, environmental variation, model updates, or operational disruption throughout the complete behavioral lifecycle.

BCNS governs AI behavioral continuity.

The standard establishes the conditions required to ensure that AI behavior remains predictable and governance-consistent across change rather than becoming fragmented, inconsistent, or unreliable.

Change is inevitable.

Loss of continuity is not.

Behavioral Continuity enables organizations to evolve AI systems while preserving governance stability, operational confidence, and long-term behavioral reliability.

[→ View Standard](#)

Behavioral Interoperability Standard (BIS)

Category: Governance & Enforcement

Subcategory: AI Behavioral Interoperability Governance

Defines the structural conditions under which AI behavior remains compatible, coordinated, predictable, governance-aligned, and operationally trustworthy while interacting with humans, AI systems, autonomous systems, organizations, and complex operational environments throughout the complete behavioral lifecycle.

BIS governs AI behavioral interoperability.

The standard establishes the conditions required to ensure that behavioral interoperability preserves governance integrity, accountability, operational consistency, and trustworthy collaboration across heterogeneous environments.

Technical interoperability connects systems.

Behavioral interoperability connects governance.

Behavioral Interoperability enables independent AI systems to cooperate responsibly without compromising trust, accountability, or governance integrity.

[→ View Standard](#)

Behavioral Safety Standard (BSS)

Category: Governance & Enforcement
Subcategory: AI Behavioral Safety Governance

Defines the structural conditions under which AI behavior remains safe, governable, predictable, controllable, accountable, and operationally trustworthy while minimizing unacceptable behavioral risks throughout the complete behavioral lifecycle.

BSS governs AI behavioral safety.
The standard establishes the conditions required to ensure that behavioral safety remains continuously preserved despite operational uncertainty, autonomous decision-making, environmental change, or evolving AI behavior.

Safety is not the absence of risk.

Safety is the presence of governed behavior.

Behavioral Safety enables organizations to deploy AI with confidence by ensuring that behavioral risks remain continuously identifiable, governable, and controllable throughout real-world operation.

[→ View Standard](#)

Autonomous Evolution Standard (AEVS)

Category: Governance & Enforcement
Subcategory: Autonomous Operational Governance

Defines the structural conditions under which autonomous evolution remains authorized, validated, traceable, and governable.

AEVS governs **autonomous evolution**.

Governable autonomy requires governable evolution.

[→ View Standard](#)

Autonomous Compatibility Standard (ACPS)

Category: Governance & Enforcement

Subcategory: Autonomous Operational Governance

Defines the structural conditions under which autonomous operational compatibility remains interoperable, aligned, trustworthy, and governable.

ACPS governs **autonomous operational compatibility**.

Governable autonomy requires governable compatibility.

[→ View Standard](#)

Autonomous Operational Accountability Standard (AOAS)

Category: Governance & Enforcement

Subcategory: Autonomous Operational Governance

Defines the structural conditions under which autonomous operational accountability remains attributable, verifiable, continuous, and governable.

AOAS governs **autonomous operational accountability**.

Governable autonomy requires governable accountability.

[→ View Standard](#)

Autonomous Escalation Standard (AESS)

Category: Governance & Enforcement

Subcategory: Autonomous Operational Governance

Defines the structural conditions under which autonomous operational escalation remains timely, controlled, justified, and governable.

AESS governs **autonomous operational escalation**.

Governable autonomy requires governable escalation.

[→ View Standard](#)

Autonomous Coordination Standard (ACOS)

Category: Governance & Enforcement

Subcategory: Autonomous Operational Governance

Defines the structural conditions under which autonomous operational coordination remains synchronized, controlled, trustworthy, and governable.

ACOS governs **autonomous operational coordination**.

Governable autonomy requires governable coordination.

[→ View Standard](#)

Autonomous Risk & Trust Standard (ARTS)

Category: Governance & Enforcement

Subcategory: Autonomous Operational Governance

Defines the structural conditions under which autonomous operational risk and trust remain identifiable, measurable, governable, and continuously justified.

ARTS governs **autonomous operational risk & trust**.

Governable autonomy requires governable risk and trustworthy operation.

[→ View Standard](#)

Autonomous Constraint Standard (ACS)

Category: Governance & Enforcement

Subcategory: Autonomous Operational Governance

Defines the structural conditions under which autonomous operational constraints remain defined, enforceable, monitored, and governable.

ACS governs **autonomous operational constraints**.

Governable autonomy requires governable constraints.

[→ View Standard](#)

Autonomous Execution Standard (AES)

Category: Governance & Enforcement

Subcategory: Autonomous Operational Governance

Defines the structural conditions under which autonomous operations remain authorized, controlled, monitored, and governable throughout execution.

AES governs **autonomous execution**.

Governable autonomy requires governable execution.

[→ View Standard](#)

Autonomous Authority Standard (AAS)

Category: Governance & Enforcement

Subcategory: Autonomous Operational Governance

Defines the conditions under which autonomous operational authority remains legitimate, verifiable, controllable, and governable.

AAS governs **autonomous operational authority**.

Governable autonomy requires governable authority.

[→ View Standard](#)

Autonomous Identity Standard (AIS)

Category: Governance & Enforcement

Subcategory: Autonomous Operational Governance

Defines the structural conditions under which an autonomous operational actor remains uniquely identifiable, attributable, verifiable, continuous, and governable.

AIS governs **autonomous operational identity**.

Autonomous operation begins with identity.

Governable autonomy begins with governable identity.

[→ View Standard](#)

Governance Accountability Standard (GAS-A)

Category: Governance & Enforcement

Subcategory: Governance Architecture

Defines the structural conditions under which governance-accountability relationships remain identifiable, attributable, traceable, reviewable, governable, enforceable, auditable, and operationally valid throughout the governance lifecycle.

GAS-A governs governance accountability.

The standard establishes the conditions required to determine who remains accountable for governance outcomes, governance decisions, governance actions, governance failures, governance interventions, and governance consequences throughout operational reality.

Governance authority may exist.

Governance authority may be delegated.

Accountability must remain identifiable.

Governance outcomes become governable only when accountability remains identifiable.

[→ View Standard](#)

Governance Authority Standard (GAS)

Category: Governance & Enforcement

Subcategory: Governance Architecture

Defines the conditions under which governance authority may be established, recognized, assigned, validated, delegated, transferred, restricted, revoked, and maintained within a governed system.

GAS governs governance legitimacy, authority ownership, authority assignment, authority recognition, authority stewardship, and governance authority continuity across organizations, institutions, AI systems, autonomous agents, robotics, Human-AI environments, and future governance ecosystems.

All governance begins with authority.

Governance Authority serves as the foundational governance condition upon which all governance structures depend.

[→ View Standard](#)

Governance Boundary Standard (GBS)

Category: Governance & Enforcement
Subcategory: Governance Architecture

Defines the structural conditions under which governance boundaries remain identifiable, attributable, legitimate, traceable, governable, enforceable, reviewable, auditable, and operationally valid throughout the governance lifecycle.

GBS governs governance boundaries. The standard establishes the conditions required to determine where governance authority begins, where governance authority ends, what remains inside governance jurisdiction, and what remains outside governance jurisdiction.

Governance authority alone is not sufficient.

Governance authority must operate within defined boundaries.

Governance becomes governable only when governance boundaries become visible.

[→ View Standard](#)

Governance Continuity Standard (GCS)

Category: Governance & Enforcement
Subcategory: Governance Architecture

Defines the structural conditions under which governance authority, governance responsibilities, governance knowledge, governance processes, governance controls, governance relationships, and governance operations remain continuous, transferable, recoverable, resilient, governable, traceable, and operationally valid throughout the governance lifecycle.

GCS governs governance continuity. The standard establishes the conditions required to preserve governance functionality despite organizational change, leadership succession, personnel turnover, technological evolution, operational disruption, AI replacement, governance recovery, and future organizational transformation.

Governance may remain transparent.

Governance must also remain continuous.

Governance that cannot survive change cannot remain trustworthy.

[→ View Standard](#)

Governance Delegation Standard (GDS)

Category: Governance & Enforcement
Subcategory: Governance Architecture

Defines the structural conditions under which governance authority delegations

remain legitimate, attributable, traceable, reviewable, governable, enforceable, auditable, and operationally valid throughout the governance lifecycle.

GDS governs governance delegation. The standard establishes the conditions required to determine how governance authority is transferred, delegated, distributed, assigned, restricted, revoked, and reconstructed across governance environments.

Governance authority may exist.

Governance authority may have boundaries.

Governance authority may have scope.

Governance authority must also be transferable.

Governance authority becomes operationally scalable only when governance delegation remains trustworthy.

[→ View Standard](#)

Governance Integrity Standard (GIS)

Category: Governance & Enforcement

Subcategory: Governance Architecture

Defines the structural conditions under which governance decisions, governance actions, governance processes, governance controls, governance relationships, governance outcomes, and governance environments remain protected from manipulation, corruption, unauthorized influence, unauthorized modification, misuse, and governance-invalid interference throughout the governance lifecycle.

GIS governs governance integrity. The standard establishes the conditions required to preserve governance trustworthiness by ensuring that governance remains authentic, protected, resistant to manipulation, and operationally valid throughout operational reality.

Governance may be validated.

Governance must also remain protected.

Governance correctness must be preserved after it has been achieved.

[→ View Standard](#)

Governance Interoperability Standard (GOIS)

Category: Governance & Enforcement

Subcategory: Governance Architecture

Defines the structural conditions under which multiple governance systems, governance architectures, governance authorities, governance processes, governance controls, governance records, and governance outcomes remain compatible, coordinated, translatable, alignable, traceable, governable, and operationally valid across different governance environments.

GOIS governs governance interoperability. The standard establishes the conditions required to ensure that governance systems can operate together across organizations, institutions, jurisdictions, technologies, AI systems, autonomous agents, Human-AI environments, and future governance ecosystems.

Governance may remain continuous.

Governance systems must also operate together.

Governance reaches ecosystem scale only when governance systems can operate together.

[→ View Standard](#)

Governance Scope Standard (GSS)

Category: Governance & Enforcement
Subcategory: Governance Architecture

Defines the structural conditions under which governance scope remains identifiable, attributable, legitimate, traceable, reviewable, governable, enforceable, auditable, and operationally valid throughout the governance lifecycle.

GSS governs governance scope. The standard establishes the conditions required to determine what governance may legitimately govern, what governance may not govern, what objects belong within governance scope, and what objects remain outside governance scope.

Governance authority may exist.

Governance authority may have boundaries.

Governance authority must also have scope.

Governance becomes operationally meaningful only when governance scope becomes identifiable.

[→ View Standard](#)

Governance Transparency Standard (GTS)

Category: Governance & Enforcement
Subcategory: Governance Architecture

Defines the structural conditions under which governance decisions, governance actions,

governance processes, governance controls, governance relationships, governance outcomes, and governance information remain visible, understandable, explainable, reviewable, traceable, accessible, and operationally valid throughout the governance lifecycle.

GTS governs governance transparency. The standard establishes the conditions required to ensure that governance remains sufficiently visible and understandable for legitimate governance participants while preserving governance trust, accountability, and operational clarity throughout operational reality.

Governance may remain protected.

Governance must also remain transparent.

Governance that cannot be appropriately understood cannot be sustainably trusted.

[→ View Standard](#)

Governance Validation Standard (GVS)

Category: Governance & Enforcement

Subcategory: Governance Architecture

Defines the structural conditions under which governance decisions, governance actions, governance processes, governance outcomes, governance controls, and governance relationships remain verifiable, reviewable, auditable, governable, enforceable, traceable, and operationally valid throughout the governance lifecycle.

GVS governs governance validation. The standard establishes the conditions required to determine whether governance remains correct, whether governance operates according to defined governance conditions, whether governance outcomes remain verifiable, and whether governance-validation activities remain reconstructable throughout operational reality.

Governance authority may exist.

Governance accountability may exist.

Governance must also be validated.

Governance correctness becomes trustworthy only when governance validity can be demonstrated.

[→ View Standard](#)

Relationship Accountability Standard - (RAS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance Architecture

Defines the structural conditions under which operational,

contractual, organizational, supervisory, delegated, collaborative, autonomous, Human-AI, and multi-party relationships remain identifiable, classifiable, traceable,

accountable, and governable throughout their lifecycle.

RAS governs the relationship layer of accountability and establishes the foundation required to determine authority, responsibility, capability, control, oversight, evidence, and accountability across organizations, institutions, AI systems, autonomous agents, contractor networks, and multi-layer operational environments.

Core Question:

What is the actual operational relationship between the actors?

Every accountability chain begins with a relationship.

[→ View Standard](#)

Authority Governance Standard - (AGS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance Architecture

Defines the structural conditions under which authority remains identifiable, legitimate, attributable, bounded, traceable, governable, enforceable, and operationally valid throughout operational environments.

AGS governs authority and establishes the governance layer required to determine who possesses the legitimate right to decide, approve, authorize, direct, restrict, supervise, intervene, delegate, or govern actions across organizations, institutions, AI systems, autonomous agents, structured agent systems, orchestrated agent systems, and Human-AI operational environments.

Authority determines who may act before governance determines who must act.

[→ View Standard](#)

Authority Delegation Standard - (ADS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance Architecture

Defines the structural conditions under which authority may be delegated, transferred, assigned, distributed, inherited, accepted, exercised, governed, and reconstructed while preserving legitimacy, traceability, accountability, continuity, and operational validity

throughout the delegation lifecycle.

ADS governs authority delegation and establishes the governance layer required to determine how authority moves between actors across organizations, institutions, contractor networks, AI systems, autonomous agents, orchestrated agent systems, Human-AI environments, and distributed operational structures.

Authority may be delegated, but governance visibility of delegated authority must never be lost.

[→ View Standard](#)

Authority Validation Standard - (AVS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance Architecture

Defines the structural conditions under which authority remains verifiable, legitimate, recognizable, traceable, governable, accountable, reconstructable, and operationally valid throughout its lifecycle.

AVS governs authority validation and establishes the governance layer required to determine whether authority claims, authority assignments, delegated authority structures, authority rights, certifications, permissions, approvals, and governance privileges remain valid across organizations, institutions, regulatory environments, AI systems, autonomous agents, and Human-AI operational environments.

Authority may exist and authority may be delegated, but governance cannot rely upon authority that cannot be validated.

[→ View Standard](#)

Authority Escalation Standard - (AES)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance Architecture

Defines the structural conditions under which authority may be escalated, transferred upward, referred, elevated, accepted, governed, traced, reconstructed, and operationally resolved while preserving legitimacy, traceability, accountability, continuity, and operational validity throughout the escalation lifecycle.

AES governs authority escalation and establishes the governance layer required to determine when authority has reached its limits, when escalation becomes necessary, who should receive escalation, and whether escalation remains valid across organizations, institutions, contractor networks, AI systems, autonomous agents,

orchestrated agent systems, and Human-AI operational environments.

Authority escalation exists because authority has limits.

[→ View Standard](#)

Responsibility Governance Standard - (RGS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance Architecture

Defines the structural conditions under which responsibilities remain assignable, identifiable, traceable, governable, accountable, reconstructable, enforceable, and operationally valid throughout the responsibility lifecycle.

RGS governs responsibility and establishes the governance layer required to determine who was responsible, what they were responsible for, when responsibility existed, whether responsibility remained valid, and whether responsibility was fulfilled across organizations, institutions, contractor networks, AI systems, autonomous agents, and Human-AI operational environments.

Authority grants the right to act. Responsibility creates the obligation to act.

[→ View Standard](#)

Capability Readiness Governance Standard - (CRGS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance Architecture

Defines the structural conditions under which actors, systems, organizations, contractors, AI agents, tools, resources, qualifications, competencies, permissions, and operational environments remain capable of performing assigned responsibilities in a valid, traceable, governable, accountable, and operationally reliable manner.

CRGS governs capability readiness and establishes the governance layer required to determine whether a responsible actor is actually capable of performing the assigned task, possesses the necessary qualifications, competencies, certifications, tools, resources, permissions, information, and operational conditions required for successful execution.

Responsibility creates obligation. Capability enables execution.

[→ View Standard](#)

Chain of Control Standard - (CCS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance Architecture

Defines the structural conditions under which operational control remains identifiable, traceable, governable, accountable, reconstructable, continuous, enforceable, and operationally valid throughout the execution lifecycle.

CCS governs operational control and establishes the governance layer required to determine who controlled operational reality, what was controlled, when control existed, how control was exercised, whether control remained valid, and whether the chain of control can be reconstructed across organizations, contractor networks, AI systems, autonomous agents, robotics environments, and Human-AI operational ecosystems.

Responsibility defines who must act. Capability defines who can act. Control defines who directs action.

[→ View Standard](#)

Governance Oversight Standard - (GOS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance Architecture

Defines the structural conditions under which oversight activities remain identifiable, traceable, governable, accountable, reconstructable, independent, reviewable, and operationally valid throughout the oversight lifecycle.

GOS governs governance oversight and establishes the governance layer required to determine who monitored governance activities, what was monitored, how oversight was performed, whether oversight remained independent, and whether oversight can be reconstructed across organizations, regulatory systems, certification environments, contractor networks, AI systems, autonomous agents, and Human-AI operational ecosystems.

Control directs operational reality. Oversight monitors governance reality.

[→ View Standard](#)

Evidence Accountability Standard - (EAS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance Architecture

Defines the structural conditions under which evidence remains identifiable, attributable, traceable, governable, accountable, reconstructable, reviewable, verifiable, and operationally valid throughout the evidence lifecycle.

EAS governs evidence and establishes the governance layer required to determine where evidence originated, what evidence supports a conclusion, whether evidence remains valid, how evidence can be reconstructed, and who remains accountable for evidence integrity across organizations, audits, investigations, certification systems, compliance environments, legal proceedings, AI systems, and Human-AI operational ecosystems.

Governance produces conclusions. Evidence supports conclusions.

[→ View Standard](#)

Accountability Governance Standard - (AGS-A)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance Architecture

Defines the structural conditions under which accountability relationships remain identifiable, attributable, traceable, governable, reconstructable, enforceable, reviewable, and operationally valid throughout the accountability lifecycle.

AGS-A governs accountability and establishes the governance layer required to determine who remains answerable for outcomes, decisions, actions, omissions, governance failures, operational results, and consequence-bearing events across organizations, institutions, contractor networks, certification systems, regulatory environments, AI systems, autonomous agents, and Human-AI operational ecosystems.

Responsibility defines who performs. Accountability defines who answers.

[→ View Standard](#)

Responsibility Assignment Standard - (RAS-A)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Responsibility Governance

Defines the structural conditions under which responsibilities may be assigned, allocated, transferred, accepted, recorded, governed, reconstructed, and enforced while preserving legitimacy, traceability, accountability, clarity, and operational validity throughout the responsibility-assignment lifecycle.

RAS-A governs responsibility assignment and establishes the governance layer required to determine who assigned responsibility, to whom responsibility was assigned, what responsibility was assigned, whether the assignment was valid, whether the assignment was accepted, and whether assigned responsibilities remained governable across organizations, contractor networks, institutions, AI systems, autonomous agents, and Human-AI operational environments.

Responsibility defines the duty to act. Responsibility Assignment defines who receives that duty.

[→ View Standard](#)

Responsibility Continuity Standard - (RCS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Responsibility Governance

Defines the structural conditions under which responsibilities remain preserved, connected, governable, traceable, transferable, reconstructable, enforceable, and operationally valid throughout the responsibility lifecycle despite organizational, operational, contractual, technological, supervisory, or governance changes.

RCS governs responsibility continuity and establishes the governance layer required to determine whether responsibility remained continuously preserved from assignment to outcome, whether responsibility survived transfers, substitutions, escalations, reorganizations, automation events, and governance transitions, and whether responsibility remained governable throughout operational reality.

Responsibility Assignment determines who receives responsibility. Responsibility Continuity determines whether responsibility remains preserved.

[→ View Standard](#)

Responsibility Traceability Standard - (RTS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Responsibility Governance

Defines the structural conditions under which responsibility relationships, responsibility assignments, responsibility transfers, responsibility decisions, responsibility actions, responsibility transitions, responsibility outcomes, and responsibility-governance activities remain traceable, reconstructable, reviewable, auditable, governable, enforceable, and operationally valid throughout the responsibility lifecycle.

RTS governs responsibility traceability and establishes the governance layer required to determine how responsibility moved throughout operational reality, who carried responsibility at specific points in time, how responsibility changed, and whether the complete responsibility chain can be reconstructed across organizations, contractor networks, institutions, AI systems, autonomous agents, and Human-AI operational environments.

Responsibility Continuity determines whether responsibility remained preserved. Responsibility Traceability determines whether responsibility can be reconstructed.

[→ View Standard](#)

Decision Accountability Standard - (DAS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance

Defines the structural conditions under which decisions, decision authorities, decision processes, decision inputs, decision approvals, decision outcomes, and decision-governance activities remain attributable, accountable, traceable, reconstructable, reviewable, governable, enforceable, and operationally valid throughout the decision lifecycle.

DAS governs decision accountability and establishes the governance layer required to determine who made a decision, who approved a decision, under what authority the decision was made, what information was used, what consequences emerged, and who remains accountable for the decision across organizations, institutions, contractor networks, AI systems, autonomous agents, and Human-AI operational environments.

Accountability asks who remains answerable. Decision Accountability asks who remains answerable for the decision.

[→ View Standard](#)

Accountability Continuity Standard - (ACS)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance

Defines the structural conditions under which accountability relationships remain preserved, connected, governable, traceable, transferable, reconstructable, enforceable, reviewable, and operationally valid throughout the accountability lifecycle despite organizational, operational, contractual, technological, supervisory, regulatory, or governance changes.

ACS governs accountability continuity and establishes the governance layer required to determine whether accountability remained continuously preserved from decision to outcome, whether accountability survived transfers, delegations, escalations, reorganizations, substitutions, Human-AI transitions, and governance changes, and whether accountability remained governable throughout operational reality.

Responsibility Continuity determines whether responsibility remains preserved. Accountability Continuity determines whether accountability remains preserved.

[→ View Standard](#)

Accountability Chain Standard - (ACS-C)

Category: Governance & Enforcement

Family: Accountability Governance Architecture (AGA™)

Subcategory: Accountability Governance

Defines the structural conditions under which accountability relationships remain connected, traceable, reconstructable, reviewable, governable, enforceable, attributable, auditable, and operationally valid across multi-layer governance structures throughout the accountability lifecycle.

ACS-C governs accountability chains and establishes the governance layer required to determine how accountability travels across organizations, departments, management layers, contractor networks, subcontractor chains, holding structures, regulatory environments, AI systems, autonomous agents, Human-AI ecosystems, and other multi-layer governance environments.

Accountability Continuity determines whether accountability remained preserved. Accountability Chain determines how accountability travels across governance structures.

[→ View Standard](#)

OOF™ standards define structured methodological conditions across identity, validation, value, and governance architectures.

Each standard operates as an independent, non-executable structural framework.

Agent Memory Integrity Standard (AMIS)

Category: AI & Interpretation

Subcategory: Agent Memory Governance Architecture

Defines the conditions under which memory utilized by autonomous agents

remains continuous, retrievable, updateable, coherent, accountable, reality-connected, governable, and operationally valid during agent operation.

AMIS addresses agent memory continuity, retrieval, updates, consistency, contextual persistence, operational utilization, and long-term reliability across autonomous agents, robotics, and multi-agent environments.

Agent cognition depends on memory. Agent memory depends on integrity. Together, CLIA® and MGIA™ provide a structured governance map of cognition and memory for future intelligence ecosystems.

[→ View Standard](#)

Collective Memory Integrity Standard (CMIS)

Category: AI & Interpretation

Subcategory: Collective Memory Governance Architecture

Defines the conditions under which memory shared across societies, institutions, civilizations, organizations, cultures, and collective intelligence environments remains coherent, continuous, reconstructable, accountable, retrievable, and operationally valid across generations.

CMIS governs collective knowledge, institutional memory, cultural memory, scientific memory, collective recall, civilizational continuity, and long-term preservation of collective intelligence.

A civilization that loses its memory progressively loses its intelligence.

[→ View Standard](#)

Group Memory Integrity Standard (GMIS)

Category: AI & Interpretation

Subcategory: Group Memory Governance Architecture

Defines the conditions under which memory shared by a group remains coherent, continuous, reconstructable, accountable, retrievable, and operationally valid throughout collaboration, coordination, communication, and collective activity.

GMIS governs shared memory, collective recall, group context, coordination memory, and accountability across teams, organizations, Human-AI groups, multi-agent environments, and future collective intelligence systems.

Collective intelligence depends on collective memory.

[→ View Standard](#)

Memory Evolution Integrity Standard (MEIS)

Category: AI & Interpretation

Subcategory: Memory Evolution Governance Architecture

Defines the conditions under which memory remains capable of evolving, adapting, learning, refining, expanding, reorganizing, and improving while preserving continuity, traceability, accountability, and operational validity throughout the memory lifecycle.

MEIS governs memory change, adaptation, learning, refinement, optimization, continuity preservation, evolution traceability, and accountability across AI systems, autonomous agents, Human-AI environments, organizations, and future adaptive intelligence ecosystems.

Intelligence depends not only on memory, but on how memory evolves.

[→ View Standard](#)

Memory Governance Standard (MGS)

Category: AI & Interpretation

Subcategory: Memory Governance Architecture

Defines the conditions under which memory systems, memory operations, memory access, memory modification, memory preservation, memory utilization, and memory evolution remain governable, accountable, auditable, controllable, and operationally valid throughout the memory lifecycle.

MGS governs memory authority, memory access, oversight, auditability, accountability, stewardship, governance controls, and governance visibility across AI systems, autonomous agents, robotics, Human-AI environments, organizations, institutions, and future intelligence ecosystems.

Memory influences intelligence. Governance influences memory.

[→ View Standard](#)

Memory Integrity Standard (MIS)

Category: AI & Interpretation

Subcategory: Memory Governance Architecture

Defines the conditions under which memory remains traceable, retrievable, coherent, accountable, reality-connected, governable, and operationally valid throughout memory creation, storage, retrieval, modification, preservation, and utilization processes.

MIS addresses memory continuity, memory traceability, memory accountability, memory boundaries, memory states, memory preservation, memory utilization, and long-term memory validity across human, artificial, collective, organizational, institutional, and future memory environments.

[→ View Standard](#)

Multimodal Memory Integrity Standard (MMIS)

Category: AI & Interpretation

Subcategory: Multimodal Memory Governance Architecture

Defines the conditions under which memory composed of multiple modalities remains coherent, synchronized, traceable, reconstructable, interpretable, and operationally valid throughout the memory lifecycle.

MMIS governs relationships between text, images, audio, video, documents, sensor data, spatial information, and future multimodal memory environments across AI systems, autonomous agents, robotics, Human-AI environments, and future intelligence ecosystems.

Future intelligence is multimodal.

[→ View Standard](#)

Skill Formation Integrity Standard (SFIS)

Category: AI & Interpretation

Subcategory: Skill Formation Governance Architecture

Defines the conditions under which knowledge, experience, learning, adaptation, practice, memory utilization, and operational execution become reliable, transferable, measurable, accountable, repeatable, and operationally valid skills throughout the skill formation lifecycle.

SFIS governs skill acquisition, skill development, skill transfer, capability formation, competence validation, performance reliability, operational execution, and accountability across humans, AI systems, autonomous agents, robotics, organizations, and future intelligence ecosystems.

Knowledge creates potential. Skills create capability.

Capability creates outcomes.

[→ View Standard](#)

TMIS — Temporal Memory Integrity Standard

Category: AI & Interpretation

Subcategory: Temporal Memory Governance Architecture

Defines the conditions under which memory remains correctly associated with time, chronology, sequence, duration, temporal context, and historical continuity throughout the memory lifecycle.

TMIS governs temporal memory, chronology preservation, timeline integrity, historical continuity, causality relationships, temporal reconstruction, and sequence validity across AI systems, autonomous agents, Human-AI environments, organizations, and future intelligence ecosystems.

Memory derives meaning from time.

[→ View Standard](#)

User Memory Integrity Standard (UMIS)

Category: AI & Interpretation

Subcategory: User Memory Governance Architecture

Defines the conditions under which user-related memory remains accurate, contextualized, continuous, accountable, and operationally valid throughout long-term Human-AI interactions.

UMIS governs user preferences, user context, user intent, interaction history, personalization continuity, and user-memory accountability across AI systems, autonomous agents, robotics, and future personalized intelligence environments.

Trustworthy Human-AI relationships require trustworthy user memory.

[→ View Standard](#)

Cognitive Evolution Governance Standard - (CEGS)

Architecture Family: Cognitive Governance Intelligence Architecture (CLIA®)

Operational Layer: Cognitive Evolution Governance Layer

Category: AI & Interpretation

Subcategory: Cognitive Evolution Governance Architecture

Defines the conditions under which cognition may learn, adapt, improve, evolve, self-modify, expand capabilities, acquire knowledge, refine reasoning, and transform cognitive structures while remaining traceable, accountable, reality-connected, governance-valid, and operationally reliable.

CEGS addresses learning governance, adaptation governance, capability evolution, self-modification governance, cognitive transformation, evolution accountability, evolution traceability, long-term cognition governance, and governance of cognitive change across evolving cognition systems.

Relevant for human learning systems, AI learning systems, adaptive agents, multi-agent ecosystems, Human-AI cognition environments, organizational learning systems, institutional learning systems, autonomous cognition architectures, and future evolving intelligence ecosystems.

[→ View Standard](#)

Human-AI Cognition Integrity Standard - (HAICS)

Architecture Family: Cognitive Governance Intelligence Architecture (CLIA®)

Operational Layer: Human-AI Cognition Governance Layer

Category: AI & Interpretation

Subcategory: Human-AI Cognition Governance Architecture

Defines the conditions under which cognition emerging through interaction, cooperation, augmentation, reasoning, interpretation, decision support, and shared cognitive processes between humans and AI systems remains traceable, coherent, accountable, reality-connected, governance-valid, and operationally reliable.

HAICS addresses shared cognition, cognitive augmentation, Human-AI decision support, cognitive authority, trust calibration, reliance governance, cognition synchronization, contribution traceability, and accountability across Human-AI cognition environments.

Relevant for AI assistants, copilots, decision-support systems, enterprise AI ecosystems, healthcare environments, education systems, research environments, Human-AI teams, autonomous collaboration systems, and future Human-AI cognition ecosystems.

[→ View Standard](#)

Collective Cognition Integrity Standard - (CCIS)

Architecture Family: Cognitive Governance Intelligence Architecture (CLIA®)

Operational Layer: Collective Cognition Governance Layer

Category: AI & Interpretation

Subcategory: Collective Cognition Governance Architecture

Defines the conditions under which cognition emerging from groups, organizations, institutions, communities, governance systems, networks, and collective decision environments remains traceable, coherent, accountable, reality-connected, governance-valid, and operationally reliable across distributed cognition ecosystems.

CCIS addresses collective cognition, organizational cognition, institutional cognition, group reasoning, shared interpretation, collective reality modeling, consensus formation, distributed decision-making, and collective accountability across complex coordination environments.

Relevant for organizations, governments, institutions, expert networks, AI collectives, human collectives, human-AI ecosystems, strategic councils, distributed communities, and future collective cognition ecosystems.

[→ View Standard](#)

Cognitive Reality Modeling Standard - (CRMS)

Architecture Family: Cognitive Governance Intelligence Architecture (CLIA®)

Operational Layer: Cognitive Reality Modeling Governance Layer

Category: AI & Interpretation

Subcategory: Cognitive Reality Modeling Governance Architecture

Defines the conditions under which cognition constructs, maintains, updates, validates, and governs internal representations of reality in a manner that remains traceable, coherent, reality-connected, adaptable, governance-valid, and operationally reliable across human, agent, and multi-agent cognition environments.

CRMS addresses reality representation, world-model governance, model adaptation, model-reality alignment, predictive reality modeling, reality drift detection, simulation validity, and internal reality-model integrity across complex cognitive systems.

Relevant for humans, AI systems, autonomous agents, multi-agent environments, digital twins, simulation systems, forecasting platforms, intelligence environments, strategic planning systems, and future autonomous cognition ecosystems.

[→ View Standard](#)

Cognitive Reasoning Integrity Standard - (CRIS)

Architecture Family: Cognitive Governance Intelligence Architecture (CLIA®)

Operational Layer: Cognitive Reasoning Governance Layer

Category: AI & Interpretation

Subcategory: Cognitive Reasoning Governance Architecture

Defines the conditions under which reasoning processes, inference chains, logical transitions, conclusion formation, assumption management, evidence utilization, and cognitive justification remain traceable, coherent, reconstructable, governance-valid, and operationally reliable across human, agent, and multi-agent cognition environments.

CRIS addresses inference integrity, assumption governance, evidence-based reasoning, logical consistency, conclusion validity, reasoning traceability, reasoning drift, and cognition justification across complex cognitive systems.

Relevant for humans, AI systems, autonomous agents, multi-agent environments, strategic planning systems, intelligence environments, decision-support systems, governance systems, reasoning engines, and future autonomous cognition ecosystems.

[→ View Standard](#)

Cognitive Interpretation Integrity Standard - (CIIS)

Architecture Family: Cognitive Governance Intelligence Architecture (CLIA®)

Operational Layer: Cognitive Interpretation Governance Layer

Category: AI & Interpretation

Subcategory: Cognitive Interpretation Governance Architecture

Defines the conditions under which signals, context, instructions, intentions, observations, events, and operational reality inputs are interpreted into meaning in a manner that remains traceable, contextually valid, semantically coherent, governance-compatible, and operationally reliable across human, agent, and multi-agent cognition environments.

CIIS addresses signal interpretation, context interpretation, intent interpretation, ambiguity governance, semantic stability, meaning construction, interpretation drift, and cognition-valid meaning formation across complex cognitive systems.

Relevant for humans, AI systems, autonomous agents, multi-agent environments, decision-support systems, knowledge systems, governance environments,

cognitive assistants, interpretation engines,
and future autonomous cognition ecosystems.

[→ View Standard](#)

Multi-Agent Cognition Integrity Standard - (MCIS)

Architecture Family: Cognitive Governance Intelligence Architecture (CLIA®)

Operational Layer: Multi-Agent Cognition Governance Layer

Category: AI & Interpretation

Subcategory: Multi-Agent Cognition Governance Architecture

Defines the conditions under which cognition distributed across multiple autonomous agents remains coherent, synchronized, governable, traceable, conflict-resilient, and operationally valid during collaboration, delegation, coordination, information exchange, planning, and collective execution.

MCIS addresses cognitive synchronization, coordination integrity, delegation governance, cognitive conflict management, collective reasoning, and distributed cognition validity across autonomous multi-agent environments.

Relevant for multi-agent systems, agent orchestration platforms, autonomous coordination systems, agent swarms, enterprise agent ecosystems, distributed reasoning architectures, collaborative AI environments, delegated execution networks, and future machine societies.

[→ View Standard](#)

Agent Cognition Integrity Standard - (ACIS)

Architecture Family: Cognitive Governance Intelligence Architecture (CLIA®)

Operational Layer: Agent Cognition Governance Layer

Category: AI & Interpretation

Subcategory: Agent Cognition Governance Architecture

Defines the conditions under which autonomous agent cognition remains valid, governable, traceable, bounded, interpretable, and operationally reliable during reasoning, planning, tool use, delegation, execution, adaptation, and multi-agent interaction.

ACIS addresses cognitive traceability, authority alignment, tool cognition governance, operational interpretability, autonomous reliability, and agent cognition drift across autonomous operational environments.

Relevant for autonomous AI agents, enterprise agents, tool-using agents, agentic AI systems, multi-agent environments, orchestration systems, AI coworkers, delegated execution systems, and future autonomous agent ecosystems.

[→ View Standard](#)

Human Cognition Integrity Standard - (HCIS)

Architecture Family: Human Cognition Governance

Operational Layer: Human Cognition Integrity Layer

Category: AI & Interpretation

Subcategory: Human Cognition Governance Architecture

Defines the conditions under which human cognition remains self-governed, reality-aligned, judgment-capable, cognitively autonomous, and operationally valid during interaction with AI systems, information systems, autonomous agents, and future cognition-enhancing technologies.

HCIS addresses judgment integrity, metacognitive awareness, cognitive autonomy, reality alignment, responsibility ownership, and cognitive dependency drift in human cognition environments.

Relevant for AI-assisted decision-making, human-AI collaboration, education, professional analysis, cognitive augmentation systems, organizational decision environments, autonomous-system supervision, and future human cognition governance architectures.

[→ View Standard](#)

Cognitive Integrity Standard - (CIS)

Category: AI & Interpretation

Subcategory: Cognitive Validity & Integrity Architecture

Defines the conditions under which cognition remains valid, coherent, bounded, traceable, and governable across human, AI, agent, collective, and future cognitive architectures.

CIS addresses truth admissibility, reasoning consistency, governance boundaries, cognitive continuity, structural coherence, and cognitive invalidity drift.

Relevant for AI reasoning systems, autonomous agents, human-AI cognition environments, interpretive systems, multi-agent cognition, and future cognition governance architectures.

[→ View Standard](#)

Operational Authority Integrity Standard - (OAIS)

Category: Governance & Enforcement

Subcategory: Operational Authority Integrity Architecture

Defines the conditions under which runtime authority, delegated authority, escalation authority, and distributed authority coordination remain stable, traceable, governable, and operationally aligned across autonomous operational environments.

OAIS governs who may authorize, delegate, escalate, override, or execute consequence-bearing operational actions during runtime operation.

Addresses risks such as authority drift, delegation corruption, escalation invalidity, unauthorized execution, and distributed authority fragmentation.

Relevant for AI agents, multi-agent systems, orchestration infrastructures, enterprise AI, autonomous organizations, and robotics environments.

[→ View Standard](#)

Operational Decision Integrity Standard - (ODIS)

Category: Governance & Enforcement

Subcategory: Operational Decision Integrity Architecture

Defines the conditions under which runtime decisions remain stable, traceable, governable, and aligned across autonomous operational environments.

ODIS addresses decision drift, authority-invalid decisions, adaptive decision instability, and consequence-bearing misalignment.

Relevant for AI agents, robotics, orchestration, autonomous systems, and distributed cognition.

[→ View Standard](#)

Operational Perception Integrity Standard - (OPIS)

Category: Governance & Enforcement

Subcategory: Operational Perception Integrity Architecture

Defines the conditions under which operational perception, sensor interpretation, multimodal perception, distributed perception coordination, and consequence-bearing perception states remain stable, traceable, and aligned with runtime reality.

OPIS ensures that systems do not only process sensory inputs, but perceive operational reality in a governable and valid way.

Relevant for robotics, autonomous vehicles, multimodal AI, realtime sensing systems, industrial monitoring, autonomous agents, and distributed cognition.

[→ View Standard](#)

Operational Attention Governance Standard - (OAGS)

Category: Governance & Enforcement

Subcategory: Operational Attention Governance Architecture

Defines the conditions under which operational attention allocation, runtime prioritization, signal relevance selection, escalation sensitivity, distributed attention coordination, and consequence-bearing attention states remain materially stable, traceable, and operationally aligned across runtime systems.

OAGS governs not only what systems execute, remember, or intend, but also what systems prioritize, monitor, ignore, escalate, and treat as operationally relevant during runtime operation.

The standard addresses risks such as:

- attention drift
- signal blindness
- escalation omission
- relevance corruption
- distributed attention fragmentation
- overload amplification
- priority instability
- consequence-bearing omission

Relevant for AI agents, orchestration systems, autonomous runtime infrastructures, robotics systems, realtime monitoring environments, and distributed cognition ecosystems.

[→ View Standard](#)

Cognitive Efficiency Economy Standard - (CEES)

Category: Economic & Value Systems

Subcategory: Intelligence Efficiency & Cognitive Resource Economics

Defines the conditions under which intelligence generation, inference, orchestration, distributed cognition, and cognitive resource use remain economically sustainable and value-aligned.

CEES ensures that AI systems do not scale intelligence by creating uncontrolled cognitive waste, unnecessary inference, excessive centralization, or inefficient orchestration.

Relevant for AI agents, distributed cognition, edge AI, orchestration networks, autonomous systems, enterprise AI, and realtime assistants.

[→ View Standard](#)

Operational Intent Integrity Standard - (OIS)

Category: Governance & Enforcement

Subcategory: Operational Intent Integrity Architecture

Defines the conditions under which operational intent, delegated intent, adaptive intent evolution, and consequence-bearing intent states remain stable, traceable, and governable across execution environments.

OIS ensures that systems do not preserve only execution continuity while losing the original operational intent underneath.

Relevant for AI agents, orchestration, autonomous systems, robotics,

enterprise AI, and distributed cognition.

[→ View Standard](#)

Operational Memory Integrity Standard - (OMIS)

Category: Governance & Enforcement

Subcategory: Operational Memory Integrity Architecture

Defines the conditions under which operational memory, runtime memory continuity, contextual memory persistence, and distributed memory coordination remain stable, traceable, and governable across time.

OMIS ensures that systems do not preserve only memory storage while losing operational memory validity underneath.

Relevant for AI agents, persistent assistants, multi-agent systems, robotics, orchestration environments, and long-term autonomous systems.

[→ View Standard](#)

Operational Context Integrity Standard - (OCIS)

Category: Governance & Enforcement

Subcategory: Operational Context Integrity Architecture

Defines the conditions under which operational context, runtime environment, contextual assumptions, and consequence-bearing execution conditions remain stable, traceable, and governable.

OCIS ensures that systems do not preserve only execution activity while losing contextual validity underneath.

Relevant for AI systems, robotics, autonomous environments, orchestration, adaptive execution, and enterprise runtime systems.

[→ View Standard](#)

Operational State Transition Standard - (OSTS)

Category: Governance & Enforcement

Subcategory: Operational State Transition Architecture

Defines the conditions under which operational state transitions, runtime progression, escalation-state changes, adaptive execution shifts, and consequence-bearing operational evolution remain stable, traceable, and governable across live execution environments.

OSTS ensures that systems do not preserve only valid operational states while losing transition continuity and operational stability during runtime progression itself.

Relevant for AI runtime systems, orchestration environments, autonomous

systems, escalation-driven infrastructures, robotics, and adaptive operational architectures.

[→ View Standard](#)

Operational Dependency & Coordination Standard - (ODCS)

Category: Governance & Enforcement

Subcategory: Operational Dependency & Coordination Architecture

Defines the conditions under which operational dependencies, orchestration relationships, runtime coordination, and delegated execution continuity remain stable and governable across interconnected systems.

ODCS ensures that systems do not preserve only connectivity while losing dependency-bound operational coordination underneath.

Relevant for AI orchestration, multi-agent systems, distributed infrastructures, enterprise runtime coordination, and autonomous operational environments.

[→ View Standard](#)

Semantic Integrity Standard - (SEIS)

Category: AI & Interpretation

Subcategory: Semantic Integrity & Meaning Continuity

Defines the conditions under which operational meaning, interpretation, definitions, and semantic boundaries remain stable across human, AI, machine, and cross-system environments.

SEIS ensures that systems do not preserve only words, labels, or syntax while losing operational meaning continuity.

Relevant for AI interpretation, orchestration, semantic routing, human-AI systems, autonomous agents, and cross-system governance.

[→ View Standard](#)

Operational Evidence & Auditability Standard - (OEAS)

Category: Governance & Enforcement

Subcategory: Evidence Continuity & Operational Auditability

Defines the conditions under which operational evidence, runtime events, execution states, authority changes, and consequence-bearing actions remain reconstructable, attributable, and reviewable.

OEAS ensures that auditability is not just record storage, but preserved operational evidence continuity.

Relevant for AI systems, orchestration environments, distributed infrastructures, autonomous execution, and enterprise runtime systems.

[→ View Standard](#)

Operational Permission & Consent Standard - (OPCS)

Category: Governance & Enforcement

Subcategory: Permission Governance & Executable Consent Architecture

Defines the structural conditions under which permissions, consent states, delegated operational rights, runtime authorization, and revocable access remain traceable, executable, and governable.

OPCS ensures that permission is not only a one-time approval, but a continuously valid operational condition during execution.

The standard is relevant for AI agents, autonomous systems, orchestration environments, continuous interaction systems, distributed runtimes, and machine-executed operations.

[→ View Standard](#)

System Recovery & Continuity Standard - (SRCS)

Category: Governance & Enforcement

Subcategory: Recovery Governance & Operational Continuity

Defines the structural conditions under which systems recover from failure, corruption, desynchronization, rollback, or runtime disruption while preserving operational validity.

SRCS ensures that recovery is not only the return of system activity, but the restoration of traceable, synchronized, admissible, and governable operational continuity.

The standard is relevant for AI systems, autonomous runtimes, orchestration environments, distributed infrastructure, robotics, enterprise systems, and cognitive mesh architectures.

[→ View Standard](#)

Operational Reality Synchronization Standard - (ORSS)

Category: Governance & Enforcement

Subcategory: Operational Reality Synchronization Architecture

Defines the conditions under which distributed operational reality states remain synchronized, coherent, traceable, and governable across multi-agent runtime environments.

ORSS addresses synchronization drift, distributed reality divergence, orchestration desynchronization, and multi-agent operational mismatch.

Relevant for AI agents, robotics swarms, autonomous factories, enterprise orchestration, and distributed cognition.

[→ View Standard](#)

Operational Risk & Trust Integrity Standard - (ORTIS)

Architecture Family: Operational Reality Standards™

Operational Layer: Autonomous Systems Governance Layer

Category: Governance & Enforcement

Subcategory: Operational Risk & Trust Governance Architecture

Defines the conditions under which operational trust, runtime risk, permission eligibility, sensitivity classification, trust degradation, and consequence-bearing risk states remain traceable, governable, and operationally valid across autonomous and semi-autonomous operational environments.

ORTIS addresses trust degradation, risk escalation, permission eligibility, sensitivity mismatch, trust-risk drift, and execution legitimacy under changing runtime conditions.

Relevant for AI agents, multi-agent systems, autonomous execution environments, enterprise AI infrastructures, delegated authority systems, robotics ecosystems, and consequence-bearing autonomous operations.

[→ View Standard](#)

Operational Validity Continuity Standard - (OVCS)

Category: Governance & Enforcement

Architecture Family: Operational Reality Standards™

Operational Layer: Operational Validity Governance Layer

Governed Space: Continuous Operational Validity

Subcategory: Runtime Operational Validity Continuity

Defines the conditions under which operational validity remains continuously governable through realtime operational verification, execution admissibility, contextual integrity, and active runtime operational conditions rather than relying solely on historical certification states or static qualification events.

OVCS establishes the architectural distinction between:

Certification Reality

and

Operational Reality

by defining operational legitimacy as a continuously evolving runtime condition rather than a permanently preserved historical certification state.

Relevant for ai systems, robotics, medicine, industrial infrastructures, pilots, enterprise execution systems, autonomous factories, and consequence-bearing operational environments.

[→ View Standard](#)

Operational Cognitive Load Governance Standard - (OCLGS)

Category: Governance & Enforcement

Architecture Family: Operational Reality Standards™

Operational Layer: Cognition Governance Layer

Governed Space: Cognitive Load

Subcategory: Operational Cognitive Load Governance Architecture

Defines the conditions under which runtime cognitive load, orchestration saturation, prioritization pressure, distributed cognitive stress, and operational overload stability remain traceable, governable, and operationally valid across autonomous runtime environments.

OCLGS addresses prioritization overload, orchestration saturation, attention collapse, inference instability, escalation overload, distributed cognitive fragmentation, and runtime coordination exhaustion.

Relevant for autonomous AI systems, multi-agent orchestration, enterprise AI coordination, distributed cognition infrastructures, realtime operational systems, and adaptive runtime environments.

[→ View Standard](#)

Operational Constraint Integrity Standard - (OCNS)

Architecture Family: Operational Reality Standards™

Operational Layer: Cognition Governance Layer

Category: Governance & Enforcement

Subcategory: Operational Constraint Integrity Architecture

Defines the conditions under which runtime constraints, bounded autonomy, execution limits, operational restriction continuity, and safety-envelope stability remain traceable, governable, and operationally valid across autonomous runtime environments.

OCNS addresses constraint drift, runtime limit bypass, bounded autonomy

failure, restriction fragmentation, and adaptive constraint degradation.

Relevant for autonomous AI systems, robotics, enterprise orchestration, delegated agents, secure runtime environments, and consequence-bearing operational systems.

→ [View Standard](#)

Operational Escalation Integrity Standard - (OESIS)

Architecture Family: Operational Reality Standards™

Operational Layer: Cognition Governance Layer

Category: Governance & Enforcement

Subcategory: Operational Escalation Integrity Architecture

Defines the conditions under which runtime escalation continuity, escalation legitimacy, emergency operational escalation, and distributed escalation coordination remain stable, traceable, and governable across autonomous operational environments.

OESIS addresses escalation drift, unauthorized override escalation, distributed escalation fragmentation, emergency escalation instability, and escalation-authority divergence.

Relevant for autonomous AI systems, enterprise orchestration, emergency operational infrastructures, multi-agent coordination, and adaptive runtime environments.

→ [View Standard](#)

Cognitive Mesh Architecture Standard - (CMA)

AI & Interpretation · Distributed Cognitive Systems & Orchestration

Defines the structural conditions under which distributed AI agents, specialized cognitive modules, edge systems, orchestration layers, local intelligence environments, and cloud infrastructures cooperate as one coherent operational intelligence architecture.

CMA establishes a governance framework for scalable distributed cognition focused on orchestration quality, locality-first execution, cognitive efficiency, semantic synchronization, and validated intelligence routing rather than permanent brute-force centralization.

The standard recognizes that future intelligence scalability will increasingly depend on: specialized cognition orchestration precision distributed execution validated data quality runtime synchronization adaptive escalation CMA also integrates ArtData as a high-integrity cognitive input layer capable of reducing semantic noise, cognitive waste, redundant inference, and inefficient orchestration caused by low-quality data environments.

The standard applies to multi-agent AI systems, edge AI,

orchestration frameworks, autonomous runtime ecosystems, collaborative reasoning architectures, cloud-edge cognition systems, and participatory intelligence networks.

[→ View Standard](#)

Operational Responsibility Continuity Standard (ORCS)

Category: Governance & Enforcement

Subcategory: Operational Responsibility & Fragmented Dependency Structures

Defines the structural conditions under which operational responsibility remains continuous across fragmented, delegated, subcontracted, or formally separated systems.

ORCS extends the Operational Boundary Synchronization Standard (OBS) by defining how responsibility persists after systems become operationally synchronized. It prevents symbolic separation from hiding real execution continuity, dependency propagation, synchronized benefit, or cascading operational consequence.

The standard is especially relevant for subcontracting, temp-agency structures, platform ecosystems, supply chains, federated systems, and AI-agent execution chains.

ORCS does not prohibit fragmentation; it defines when fragmentation becomes responsibility-obscuring architecture.

[→ View Standard](#)

Operational Boundary Synchronization Standard (OBS)

Governance & Enforcement · Interdependent Operational Structures

Defines the structural conditions under which independent operational systems establish boundaries, become interconnected, synchronize operational consequence, absorb other systems, fragment into separated structures, or preserve coordinated operational continuity across multiple entities.

OBS establishes a governance architecture for interpreting operational synchronization, dependency propagation, fragmentation behavior, and cascading consequence across formally independent but operationally interconnected systems.

The standard recognizes that legal, organizational, or structural separation does not automatically eliminate operational synchronization once systems begin sharing dependency, infrastructure, survival conditions, or operational consequence.

[→ View Standard](#)

HAIWS — Human–AI Interaction Wellbeing Standard

Defines the structural conditions under which AI systems, agents, assistants, platforms, and continuous interaction environments must preserve human cognitive stability, emotional safety, attention integrity, autonomy, and long-term wellbeing.

HAIWS establishes a governance architecture for AI interaction that must not optimize engagement, dependency, persuasion, or retention at the cost of human cognitive wellbeing.

The standard is relevant for AI companions, assistants, education, coaching, workplace AI, continuous interaction systems, persuasive AI, and emotionally adaptive AI environments.

[→ View Standard](#)

AALS — Authority & Accountability Layer Standard

Governance & Enforcement · Authority, Responsibility & Operational Control

Defines the foundational governance conditions under which authority, operational control, execution legitimacy, delegation, escalation, and accountability remain traceable across human, AI, autonomous, organizational, robotic, and hybrid systems.

AALS establishes the constitutional governance layer connecting identity, authority, execution, accountability, and runtime responsibility into one traceable operational reality structure.

The standard ensures that no operational action may exist without traceable authority and accountable responsibility.

It is especially relevant for AI agents, orchestration systems, autonomous runtimes, robotic infrastructures, human–AI governance, and distributed execution environments.

[→ View Standard](#)

Operational Convergence Standard (OCS™)

Economic & Value Systems · Autonomous Market Coordination & Behavioral Synchronization

Defines the structural conditions under which independent systems may begin exhibiting synchronized or convergencelike behavior without explicit coordination.

It establishes a foundational parent standard for detecting, interpreting, auditing, and governing convergence across autonomous and semi-autonomous economic systems.

OCS™ recognizes that shared signals, optimization pressures, datasets, and feedback loops may produce materially aligned outcomes even among formally independent actors.

[→ View Standard](#)

ART — Audit in Real Time Standard

Governance & Enforcement · Real-Time Audit & Validation

Defines the structural conditions under which events, states, actions, and outputs are verified at the moment they occur.

It establishes audit as a live structural condition rather than a retrospective reporting process.

The standard requires event-time capture, state linkage, traceable origin, and verifiable audit output.

ART defines the foundational parent standard for real-time audit logic within the OOF® system.

[→ View Standard](#)

Trust Layer Standard (TLS™)

Governance & Enforcement · Trust Architecture & Validation Systems

Defines the structural conditions under which systems, institutions, AI agents, operational environments, value flows, and governance architectures become continuously trustworthy through validation, integrity, identity continuity, canonical meaning consistency, auditability, and traceable operational states.

It establishes trust as a validated operational outcome rather than a declared, symbolic, or institutionally inherited condition.

The standard requires trust to emerge from aligned methodology, validation, integrity, meaning, execution, and audit rather than from branding, reputation, or static certification alone.

TLS™ operates as a foundational parent standard for continuously verifiable trust across future human, AI, and interoperable system environments.

[→ View Standard](#)

Operational Reality Standard (ORS™)

Governance & Enforcement · Operational Reality Architecture

Defines the structural conditions under which a system, process, environment, workflow, or runtime chain remains valid not only in design, documentation, or declared state, but in actual live operation.

It establishes a foundational parent standard for determining whether declared operation and actual runtime behavior remain aligned under real governing conditions, execution boundaries, and consequence-bearing outputs.

The standard distinguishes operational reality from operational appearance by requiring identifiable runtime state, active boundary validity, effective governance conditions, and traceable alignment between what the system claims to do and what it is actually doing.

ORS™ operates as a foundational architecture for systems that must remain real in operation rather than merely structured, approved, or controlled in theory.

[→ View Standard](#)

Continuous Interaction Layer (CIL™)

AI & Interpretation · Continuous Interaction & Presence Systems

Defines the architectural conditions under which intelligent systems may maintain continuous, realtime, multi-stream, proactive, and presence-aware interaction with humans, environments, autonomous systems, and hybrid operational ecosystems.

It establishes a foundational parent layer for systems that no longer operate only through isolated prompt-response cycles, but instead participate continuously within active runtime interaction environments.

The standard governs presence, interruption, consent, behavioral visibility, proactive participation, and continuous coordination so that live interaction remains safe, interpretable, controllable, and structurally governable.

CIL™ operates as a foundational architecture for future continuous AI assistants, multimodal systems, realtime environments, robotics interaction systems, and autonomous participation ecosystems.

[→ View Standard](#)

Structured Reality Standard (SRS™)

Governance & Enforcement · Reality Validation Architecture

Defines the structural conditions under which information, claims, systems, decisions, states, and outputs remain connected to verifiable reality through defined structure, stable meaning, traceable origin, evidence continuity, and governed validation logic.

It establishes a foundational parent standard for determining whether a declared reality condition is structurally fit for validation before truth, integrity, runtime, or governance layers are applied.

The standard distinguishes structured reality from structured appearance by requiring defined reality claims, stable meaning, traceable origin, evidence continuity, and non-bypassable structural validity at the validated state.

SRS™ operates as a foundational architecture for systems that must remain reality-grounded rather than merely documented, compliant, or procedurally complete.

[→ View Standard](#)

Transparency & Probabilistic Integrity Standard

Governance & Enforcement · Transparency & Probabilistic System Integrity

Defines the structural conditions under which probabilistic prize-based, reward-based, or randomized allocation systems become transparently auditable, verifiable, and materially fair throughout their operational lifecycle.

It establishes that remaining prize or reward reality must stay continuously traceable, auditable, and materially disclosed without enabling prediction or manipulation of individual outcomes.

The standard requires initial commitment, distribution integrity, redemption integrity, remaining-state computation, disclosure, and independent auditability.

Fair Win Model™ (FWM™) serves as the protected methodology sign for commercial and licensed use under this **parent standard**.

[→ View Standard](#)

Harness Architecture Standard

Governance & Enforcement · Execution Containment & Controlled Action Environments

Defines the structural conditions under which execution is contained, isolated, bounded, permission-governed, and traceably released within a controlled operational environment.

It establishes the architecture through which valid execution is allowed to occur, not merely authorized in principle.

The standard requires execution boundaries, tool access restriction, runtime isolation, permission escalation control, and governed output release.

Harness Architecture Standard operates as a derived standard under **Execution Layer** for contained and controlled execution environments.

[→ View Standard](#)

Orchestration Governance Layer (OGL™)

Category: AI & Interpretation

Subcategory: Multi-Agent Coordination & Orchestration

Defines the governance conditions under which autonomous systems coordinate, delegate, route, sequence, and validate interactions between multiple agents, models, tools, and runtimes.

It establishes orchestration as a governance-critical layer rather than a technical workflow convenience.

The standard requires governed delegation, controlled workflow formation, authority distribution, context routing, conflict resolution, and auditable coordination. OGL™ operates as a foundational core parent standard for distributed autonomous execution within the OOF® Methodology OS™.

[→ View Standard](#)

Physical Reality Interpretation Layer (PRIL™)

AI & Interpretation · Physical Reality & Machine Perception

Defines the methodological conditions under which autonomous systems interpret physical-world signals before generating operational decisions or physical actions.

It establishes the interpretation layer through which space, movement, proximity, human presence, and environmental change become operationally usable.

The standard requires governed interpretation of physical inputs, handling of uncertainty, recognition of unsafe conditions, and execution restriction when interpretation is insufficient.

PRIL™ operates as a derived standard under **CLIA®** for embodied, spatial, and physical-world autonomous systems.

[→ View Standard](#)

Human Power Equivalency Standard (HPE™)

Economic & Value · Autonomous Operational Equivalency

Defines a standardized mechanism for representing autonomous operational capacity relative to measurable human activity.

It establishes **operational equivalency** as a representation layer, not as a measure of human worth, dignity, or value.

The standard requires measurable output, declared runtime boundaries, traceable execution conditions, and a defined equivalency methodology.

HPE™ operates as a parent standard for future sector-specific and runtime-specific equivalency modules.

[→ View Standard](#)

Ethical Layer Standard

Governance & Enforcement · Ethical Governance & Validity Conditions

Defines the structural conditions under which systems, methodologies, and technologies may be considered ethically valid within the OOF® system.

It establishes ethics as a required passage layer, not as a secondary review or optional principle.

The standard requires human harm prevention, sustainability integrity, bounded capability, and ethical legitimacy before deployment or reliance.

Ethical Layer Standard operates as a **foundational core parent standard** for derived protocols, modules, and future technologies.

[→ View Standard](#)

Value Transfer Taxation Standard (VTTS)

Economic & Value · Digital Value Systems

Defines when taxation applies across all economic systems based strictly on real value transfer.

Establishes a universal rule: only measurable, attributable, and transferred value is taxable — all other activity is excluded.

Introduces real-time taxation logic based on value capture, not reporting delays or system structure.

[→ View Standard](#)

Value Transfer Definition Standard (VTDS)

Economic & Value · Digital Value Systems

Defines what qualifies as value and when value transfer occurs within digital and hybrid systems.

Establishes a strict rule: value exists only if it is measurable, attributable, transferable, and recordable.

Separates real economic value from attention, perception, and non-transferable signals.

[→ View standard](#)

Natural Fermented Beverage Standard (NFBS)

Product & Design · Fermented Beverages

Defines the structural conditions under which a beverage created through natural fermentation may be considered biologically valid and suitable for consumption.

It separates authentic fermented beverages from uncontrolled fermentation, synthetic imitation, and misleading product claims.

The standard establishes fermentation as a real biological transformation, not as flavoring, enrichment, or marketing description.

It defines when a liquid becomes a new consumable system through controlled microbial activity.

This creates a stable category for naturally fermented beverages across traditional and modern product environments.

It also provides a parent standard under which beverage-specific modules such as kombucha can operate.

Without such structure, the category remains inconsistent, weakly defined, and vulnerable to distortion.

NFBS™ ensures that natural fermented beverages remain safe, trustworthy, and structurally valid.

[→ View standard](#)

Infused Water Standard (IWS)

Product & Design · Infused Water

Defines the structural conditions under which water may be naturally enriched through infusion while remaining water suitable for continuous hydration.

It separates authentic contact-based infusion from direct addition, synthetic enrichment, and flavored beverage simulation.

The standard protects the identity of water by requiring that enrichment occurs only through natural release from valid source material.

It creates a stable category between plain water and transformed liquid systems such as tea, extracts, or supplements.

This allows hydration products to remain clear, trustworthy, and structurally comparable across producers and applications.

It also provides a parent standard under which more specific modules such as herbal or mineral infused water can operate.

Without such structure, the category becomes vague and easily distorted by marketing language or artificial formulation.

IWS™ ensures that infused water remains natural, controlled, and valid as a hydration system.

[→ View standard](#)

Honey Integrity Standard (HIS)

Product & Design · Honey Integrity

Defines honey based on purity, biological activity, and origin transparency — not just legal definition.

Separates true honey from degraded, blended, or manipulated products through clear integrity conditions.

→ [View standard](#)

Runtime Integrity Standard™ (RIS™)

Category: Execution & Enforcement

Subcategory: Runtime Governance

Defines the governance conditions under which system execution remains traceable, verifiable, controlled, authorized,

observable, accountable, and reconstructable throughout real-world operation.

RIS™ governs runtime integrity.

The standard establishes the minimum runtime governance conditions required to ensure that execution remains

continuously governed across AI systems, autonomous systems, digital processes, enterprise systems, robotics, and

future intelligent operational environments.

Governance must remain active during execution.

Execution must remain governed.

Execution that cannot be reconstructed cannot be fully governed.

Runtime Integrity therefore becomes the foundational runtime condition of the complete OOF® architecture

ecosystem.

→ [View Standard](#)

Traffic Enforcement Integrity Standard (TEI)

Governance · Enforcement Integrity

Defines how traffic enforcement systems must operate to ensure safety, predictability, and behavioral stability.

Prevents hidden enforcement, sudden detection, and penalty-driven system design that creates reactive risk.

Establishes a non-negotiable rule:

enforcement must guide behavior, not disrupt it.

[→ View Standard](#)

Surface Integrity Standard (SIS)

Governance · Enforcement Integrity

Defines the conditions under which surfaces must remain intact, unaltered, and free from unauthorized modification.

Ensures that surfaces cannot be used for marking, communication, or alteration without explicit authorization, preserving both material and visual integrity across systems.

[→ View Standard](#)

Origin Declaration Standard (ODS™)

AI and Interpretation

Defines a simple system for declaring content origin and enabling monetization based on transparency and responsibility.

[→ View Standard](#)

INTEGROS — Integrity Standard

Governance & Enforcement

Defines the foundational conditions required for any system to be considered valid, traceable, and verifiable.

Ensures that system behavior cannot be altered without detection and establishes integrity as a precondition for trust, governance, and operation.

[→ View Standard](#)

EXECUTION LAYER — Enforcement Standard

Governance & Enforcement · Enforcement Architecture

Execution Layer™ defines the conditions under which actions in a system are permitted, executed, and validated.

It ensures that no action can occur without permission, traceability, and enforced constraints, and that all outcomes remain bound to their execution process.

The standard establishes execution as a governed, verifiable process — not just an outcome.

[→ View standard](#)

CGRM — Crisis Governance & Responsibility Standard

Governance · Enforcement Integrity

Defines the minimum conditions required to ensure that responsibility, authority, and decision-making remain clear, traceable, and enforceable during crisis situations.

Applies whenever standard governance is insufficient to maintain system stability, safety, or integrity. Ensures that responsibility is always assigned, decisions are traceable, and governance cannot be bypassed — even under pressure.

AI Compatible — requires human accountability, traceable decisions, and enforceable override mechanisms.

[→ View Standard](#)

Self-Evolving Systems Control Standard (SESCS)

Governance & Enforcement · Autonomous Systems Control

Defines the minimum control and enforcement structure for systems capable of self-modification.

Establishes a strict rule: no system evolution is permitted without real-time validation, traceability, and responsibility assignment.

Introduces a non-bypassable governance layer for AI agents and autonomous systems.

[→ View Standard](#)

Origin Asset™ Standard

Economic & Value Standards · Origin Asset™ (ORG)

This standard defines Origin Asset™ as the initial admissible state of an asset within the governed economic lifecycle.

It establishes identity, legality, and authenticity requirements at the point of system admission.

Origin Asset™ serves as the verified starting state for all subsequent value transitions.

[→ View standard](#)

DeMonet™ Standard

Economic & Value Standards · DeMonet™ (DMN)

This standard defines DeMonet™ as the governed process

through which admissible economic value is formally withdrawn from an asset.
It establishes validation and traceability requirements for structured value removal.
DeMonet™ results in ZVA™ classification within the canonical asset sequence.

[→ View standard](#)

ZVA™ (Zero Value Asset) Standard

Economic & Value Standards · Zero Value Asset (ZVA)

This standard defines ZVA™ as a formally recognized asset state in which an asset exists but carries zero admissible economic value.
It establishes structural, ethical, and integrity conditions under which value nullification occurs.
ZVA™ represents a stable and governed state within a deterministic asset lifecycle.

[→ View standard](#)

ReMonet™ Standard

Economic & Value Standards · ReMonet™ (RMN)

This standard defines ReMonet™ as the governed transition process through which economic value may be restored to a ZVA™ asset.
It establishes corrective and validation requirements prior to value reactivation.
ReMonet™ is the only permitted mechanism for transitioning back to Value Asset state.

[→ View standard](#)

Value Asset Standard

Economic & Value Standards · Value Asset (VA)

This standard defines Value Asset as the governed state in which positive admissible economic value is formally recognized.
It establishes validation requirements for lawful value activation.
Value Asset may exist only within the defined economic lifecycle architecture.

[→ View standard](#)

Economic State Architecture Standard

This standard defines the canonical lifecycle governing economic state transitions.
It establishes a deterministic and non-skippable sequence connecting asset states and transition mechanisms.
No value state may exist outside the defined architectural structure.

→ [View standard](#)

Value Governance Framework Standard

This standard defines the governance principles under which economic value decisions are validated and executed.
It establishes authority boundaries and traceability requirements for value-related transitions.
The framework prevents arbitrary or non-deterministic manipulation of asset value.

→ [View standard](#)

Origin Eco™ Standard

This standard defines the structural transparency conditions for documenting the origin of materials, material composition, and core production processes within product and production systems.

Origin Eco™ establishes an environmental transparency model focused on origin disclosure, material visibility, and production process traceability.

The standard strengthens environmental credibility by transforming implicit environmental claims into visible structural origin transparency.

Origin Eco™ does not replace environmental regulations or certification systems.

It defines the foundational transparency conditions for environmentally responsible production.

→ [View standard](#)

Water Integrity™ Standard

This standard defines the structural transparency conditions for documenting water sources, declared usage, and responsibility within water-dependent production systems.

Water Integrity™ establishes a framework for visible water provenance and declared usage transparency across agricultural, food-related, and production environments.

The standard improves supply chain transparency without replacing public health, hygiene, or environmental regulations.

Water Integrity™ introduces a minimal structural baseline for transparent disclosure of water inputs in production systems.

[→ View standard](#)

Soil Integrity™ Standard

Environmental Integrity Standards · Soil Integrity™

This standard establishes structural transparency for soil-based production systems.

It requires disclosure of soil type, fertilization inputs, and plant protection practices used in production.

Soil Integrity™ does not regulate agriculture or replace certification schemes.

It introduces a transparency baseline that makes soil inputs and cultivation practices visible and accountable.

[→ View standard](#)

Carbon Integrity™ Standard

Environmental Integrity Standards · Carbon Integrity™

This standard establishes structural transparency for soil-based production systems.

It requires disclosure of soil type, fertilization inputs, and plant protection practices used in production.

Soil Integrity™ does not regulate agriculture or replace certification schemes.

It introduces a transparency baseline that makes soil inputs and cultivation practices visible and accountable.

[→ View standard](#)

Air Integrity™ Standard

Environmental Integrity Standards · Air Integrity™

This standard establishes structural transparency for operational activities that may influence air conditions in production or service environments.

It requires disclosure of emission-related activities, mitigation mechanisms,

measurement status, and responsible entity.

Air Integrity™ does not measure air quality or define emission limits.
It introduces transparent disclosure of operational reality.

[→ View standard](#)

Whole Process Plastic Integrity™ Standard (WPPI™)

Environmental Integrity Standards · Process & Material Integrity

This standard establishes a structured methodology for evaluating plastic exposure across the full production lifecycle of a product or material system. It introduces process-based integrity tiers that classify and disclose intentional plastic use and potential contamination across materials, production equipment, packaging, storage, and logistics.

WPPI™ shifts evaluation from product-only plastic claims to full operational process transparency across the supply chain.

[→ View standard](#)

Carbon Lifecycle Integrity™ Standard (CLI™)

Environmental Integrity Standards · Carbon Lifecycle Transparency

This standard establishes a structured methodology for transparent carbon visibility across the lifecycle of a product. Carbon Lifecycle Integrity™ connects material origin, production energy use, packaging systems, and logistics pathways into a unified lifecycle framework that reveals carbon exposure per product.

Carbon Visibility Index™ Standard (CVI™)

Environmental Integrity Standards · Carbon Lifecycle Transparency

This standard establishes a structured measurement framework for expressing lifecycle carbon exposure per product. Carbon Visibility Index™ converts lifecycle transparency into a measurable and comparable carbon-per-product value, enabling objective comparison across products, production systems, and supply chains.

ArtData™ Standard

AI & Data Integrity Standards · Data Integrity Classification

This standard defines ArtData™ as a minimum structural integrity classification for datasets used in artificial intelligence training, testing, and

validation environments.

ArtData™ establishes five core structural requirements: origin disclosure, identity anchoring, time continuity, modification transparency, and responsible entity declaration.

It does not certify dataset quality or neutrality.

It establishes traceability and accountability as the minimum foundation for reliable AI data pipelines.

TVL® Truth Validation Standard

AI Interpretation Standards · Truth Validation

This standard defines a structured methodology for validating information used in decision environments, particularly in artificial intelligence systems.

Truth Validation establishes the conditions under which information, claims, or decision outputs can be considered structurally reliable, traceable, and contextually verified. Instead of relying on single-source verification or authority-based claims, the standard defines truth as the outcome of a structured validation process across independent verification layers.

Truth Validation provides the methodological foundation for evaluating the integrity of information used in automated decision systems, governance processes, and high-risk analytical environments.

OBIDENTITY™ — Origin-Bound Identity Standard

Governance & Enforcement · Identity

OBIDENTITY™ defines the minimum conditions under which an identity can exist as a non-replicable, traceable, and audit-verifiable entity.

It establishes origin-bound identity through a unique anchor, continuous event history, and independent verification across systems.

The standard enables identity to exist beyond platforms, ensuring continuity, accountability, and resistance to replication.

Clean Tea Standard

Product & Design · Clean Tea

Defines tea based on full lifecycle integrity — including source, handling, processing, and material contact — rather than packaging or appearance.

Establishes minimum conditions for contamination-free, traceable, and structurally preserved tea products.

[→ View Standard](#)

Representation & Copy Standard (RCS™)

AI and Interpretation · Representation and Copy

Defines the structural distinction between original assets, copies, and representations across physical, digital, and virtual environments.

Establishes a clear classification framework for authorship, exhibition, valuation, licensing, and public trust.

[→ View Standard](#)

Asset Identity Standard (AIS)

Defines the minimum conditions required for an asset to be uniquely identified, tracked, and governed within a system.

Ensures that assets cannot participate in validation, activation, or value flow without a verifiable identity. Prevents duplication, enables traceability, and establishes the foundation for reliable economic systems.

[→ View Standard](#)

Value Activation Standard (VAS)

Defines the conditions under which an asset becomes economically active within a governed system.

Ensures that assets cannot participate in value generation, liquidity, or distribution before passing structural validation. Separates asset existence from economic activation, creating a controlled and integrity-based value flow environment.

[→ View Standard](#)

Digital Value Interaction Standard (DVIS)

Economic & Value · Digital Value Systems

Defines the structural difference between interaction, perceived value, and real value movement in digital systems.

Establishes a clear rule: only measurable and transferable value constitutes a transaction, while all other interactions remain signals without economic reality.

Separates attention from value, and perception from measurable outcomes.
