

SVM — State Verification Module

Parent Standard: ART — Audit in Real Time Standard

Category: Governance & Enforcement

Subcategory: Real-Time State Verification

Type: Audit Integrity Module

Version: 1.0

Status: Canonical · Open Module

Effective Date: 7 May 2026

Compatibility: OOF® Methodology OS™ · ART · INTEGROS® · TVL® · OBIDENITY® · UCL™

Authority: OOF®

Protection: MIP® — Methodological Intellectual Property

Canonical Language: English (UCL™)

Canonical Definition

State Verification Module defines the structural conditions under which a live system state is verified as current, traceable, and linked to the real condition it represents at the moment of observation.

A state verification condition is valid only if:

- the observed state exists at the time of verification
- the verified state remains linked to the real operating condition
- the source of state observation is traceable
- the verification output remains structurally connected to the observed state
- delayed interpretation does not replace live state confirmation
- A reported state that cannot be structurally linked to live system reality does not satisfy SVM.

Module Function

SVM defines how system state becomes verifiable in operational reality rather than only reportable after the fact.

The module applies where an organization must prove not only that a system had a certain condition, but that this condition was actually verified while it still existed as a live state.

Step 1 — Define the State Boundary

The organization must define what system state is being verified.

Minimum requirement:

- the target state is explicit
- the state boundary is distinguishable
- the verified condition is not mixed with undefined contextual assumptions

Step 2 — Define Verification Timing

The system must define when state verification occurs.

Minimum requirement:

- verification occurs while the state is live or under structurally valid live linkage
- retrospective reconstruction is not treated as state verification
- timing logic is explicit

Step 3 — Define State Source

The originating source of state observation must be identifiable.

Minimum requirement:

- source system, process, actor, or measurement path is defined
- the source remains traceable
- detached or unverifiable observation origin is excluded from valid verification

Step 4 — Define Verification Path

The path from observed state to verified output must remain visible.

Minimum requirement:

- verification path is traceable
- no hidden substitution or silent reinterpretation occurs
- the output is not created through undefined intermediary logic

Step 5 — Preserve State Linkage

The verified output must remain linked to the actual state present at observation time.

Minimum requirement:

- state linkage exists
- the verification result is not detached from the observed condition
- later reporting does not replace live verification structure

Step 6 — Restrict Invalid State Claims

The system must not treat assumed, inferred, or post-event descriptions as valid state verification.

Minimum requirement:

- reconstructed state is distinguishable from live verified state
 - missing live verification is not silently replaced
 - validity is not claimed without structural linkage to the observed condition
-

Scenario

An organization must prove that a critical system was in a valid operating state at the exact moment a sensitive action or transition occurred.

Application

SVM is used to ensure:

- the relevant state is explicitly defined
 - the state is verified while live
 - the observation source is identifiable
 - the verification path remains traceable
-

Result

The organization gains stronger evidence that the state was not merely reported later, but verified as operational reality when it actually existed.

Scenario

An organization uses AI in a sensitive workflow and must verify the runtime state under which an output, recommendation, or action was produced.

Application

SVM is used to ensure:

- the runtime condition is explicitly defined
 - the state is verified during operation
 - the source path remains traceable
 - the verification output remains linked to the live system condition
-

Result

The organization gains a stronger basis for proving that AI-related outputs were produced under a verified real-time state rather than

inferred later through logs or interpretation.

Canonical Closing Statement

If a state is not verified while it exists, it is not structurally verified as operational reality.
