

CVIM — Control Validity Integrity Module

OriginID: OOF-OID-AGA-CVIM-2026-06-14-0038

Architecture Ecosystem: Structured Reality Standards™

Architecture Family: Accountability Governance Architecture (AGA™)

Operational Layer: Control Governance Layer

Governed Space: Control Validity Integrity

Category: Governance & Enforcement

Subcategory: Chain of Control Governance

Type: Chain of Control Standard Module

Parent Standard: Chain of Control Standard (CCS)

Version: 1.0

Status: Canonical · Open Module

Origin Date: 14 June 2026

Compatibility: OOF Methodology OS · Chain of Control Standard (CCS)

· Authority Governance Standard (AGS) ·

Authority Validation Standard (AVS) · Responsibility Governance

Standard (RGS) · INTEGROS® — Integrity Standard

AI-Readable: Yes

Authority: OOF

Protection: MIP — Methodological Intellectual Property

Canonical Language: English (UCL)

Canonical Definition

Control Validity Integrity Module (CVIM) defines the structural conditions under which operational control remains legitimate, recognized, authorized, governable, accountable, reconstructable, enforceable, and operationally valid throughout the control lifecycle.

CVIM governs control validity.

The module establishes the integrity conditions required to determine whether control was legitimately exercised, properly recognized, operationally authorized, continuously valid, and enforceable within the governance environment.

Module Operational Role

CVIM defines the control-validity governance layer of CCS.

Its role is to ensure that operational control remains legitimate and governance-valid throughout execution.

Module Operational Space

CVIM governs:

- control validity
- control legitimacy
- supervision validity
- command validity
- control authorization
- operational-control recognition
- control enforceability
- control lifecycle governance

The module applies wherever governance requires confirmation that control remained valid.

Module Function

The module applies wherever systems must preserve:

- legitimate control relationships
- recognized supervision authority
- reconstructable control history
- accountable control structures
- governance-valid control assignments
- operationally reliable control states

Its function is to ensure that governance can determine whether operational control remained valid throughout execution.

Minimum Implementation Framework

1. Define the Control Validity Object

The organization must define which control environments require validity governance.

This may include:

- management structures
- contractor environments
- subcontractor chains
- supervisory systems
- operational execution environments
- industrial operations
- AI governance systems
- Human-AI operational systems

2. Define Control Validity Conditions

The system must define the conditions under which operational

control remains valid.

This includes:

- legitimacy requirements
- authorization requirements
- recognition requirements
- accountability requirements
- governance requirements
- control-valid conditions

3. Define Validity Degradation Detection Logic

The system must define how control-validity failures are identified.

This may include:

- unauthorized supervision
- invalid control assignments
- unrecognized command relationships
- governance-invalid control structures
- expired control authority
- operational-control conflicts

4. Define Operational Response or Governance Logic

The system must define governance logic for control-validity failures.

Governance response may include:

- control review
- authorization verification
- governance intervention
- reassignment procedures
- corrective actions
- control validation
- operational invalidation where required

5. Preserve Traceability & Restrict Invalid Conditions

The system must preserve reconstructable traceability of:

- control assignments
- supervision authorizations
- governance reviews
- validation activities
- intervention procedures
- resulting control states

A control-governance environment must not remain validity-valid if materially significant control relationships cannot be reconstructed, reviewed, validated, recognized, authorized, or governed.

Use Case 1 — Industrial Supervision

Environment

Scenario

A supervisor directs operational work within a manufacturing environment involving multiple teams and production activities.

Application

CVIM determines whether supervisory control remained legitimate, authorized, and operationally valid throughout execution.

Result

Governance gains visibility into the validity of operational-control relationships.

Use Case 2 — Autonomous Agent Environment

Scenario

An orchestration platform directs autonomous agents performing operational activities across a distributed system.

Application

CVIM determines whether operational control remains authorized, recognized, and valid throughout runtime execution.

Result

Governance gains visibility into the validity of control relationships across intelligent operational systems.

Canonical Closing Statement

Control Validity Integrity Module (CVIM) defines the structural conditions under which operational control remains legitimate, recognized, authorized, governable, accountable, reconstructable, enforceable, and operationally valid throughout the control lifecycle.

**Control may exist, but not every control relationship is valid.
Control validity integrity therefore becomes a foundational**

condition of trustworthy chain-of-control governance.
