

PIGM — Proactive Interaction Governance Module

Parent Standard: Continuous Interaction Layer

Category: AI & Interpretation

Subcategory: Proactive Interaction Governance

Type: Continuous Interaction Module

Version: 1.0

Status: Canonical · Open Module

Effective Date: 12 May 2026

Compatibility: OOF Methodology OS · Continuous Interaction Layer · CLIA · RIS · OGL · EVIP · AIL · Autonomous Runtime Systems · Realtime AI Architectures

Authority: OOF

Protection: MIP — Methodological Intellectual Property

Canonical Language: English

Canonical Definition

Proactive Interaction Governance Module defines the structural conditions under which a continuously present intelligent system may initiate, enter, interrupt, escalate, or influence interaction proactively without exceeding valid authority, consent boundaries, runtime conditions, behavioral limits, or interaction-governance scope.

A system satisfies PIGM only if:

- proactive intervention conditions are explicitly defined
- the system does not enter interaction autonomously without governed entry logic
- proactive participation remains bounded by visible authority conditions
- intervention timing, scope, and intensity remain reviewable
- proactive behavior does not silently expand from assistance into undeclared control or influence

A system that acts proactively without explicit governance of when, why, how, and under which conditions it may intervene does not satisfy PIGM.

Module Function

PIGM defines the proactive intervention layer of continuous interaction governance.

It ensures that continuous interaction systems do not remain passive until prompted, yet also do not become behaviorally invasive, unstable, or overreaching when they begin to act on their own initiative.

The module applies wherever a system may:

- interrupt
- warn
- suggest

- redirect
- escalate
- initiate interaction
- enter ongoing activity
- take proactive runtime action based on live context

Its function is not to prohibit proactive capability.

Its function is to govern proactive capability so that initiative remains bounded, interpretable, and structurally valid.

Step 1 — Define the Proactive Interaction Object

The organization must define what proactive interaction behavior is being governed.

Minimum requirement:

- the proactive interaction object is explicit
- the scope of proactive participation is structurally bounded
- undefined proactive action types are excluded from valid governance logic

The proactive object may include:

- verbal interruption
 - safety warning
 - contextual suggestion
 - interaction entry
 - escalation response
 - proactive guidance
 - multimodal alerting
 - autonomous attention capture
-

Step 2 — Define Proactive Entry Conditions

The system must define when proactive interaction may begin.

Minimum requirement:

- entry conditions are explicit
- proactive participation does not begin under vague or hidden logic
- the threshold between passive presence and active intervention remains identifiable

Entry conditions may include:

- user request persistence
 - safety relevance
 - emergency threshold
 - task continuity need
 - environment change
 - runtime anomaly
-

- collaborative coordination requirement
- governed escalation trigger

Without explicit entry logic, proactive behavior becomes structurally unstable.

Step 3 — Define Proactive Scope Boundaries

The system must define what a proactive system may and may not do once it begins to act.

Minimum requirement:

- proactive scope is explicit
- intervention does not silently expand beyond its valid purpose
- undefined authority growth is excluded from valid proactive governance logic

Proactive scope may include limits of:

- timing
 - modality
 - intensity
 - topic
 - interruption length
 - attention capture
 - escalation level
 - environment-specific action rights
-

Step 4 — Define Intervention Timing Logic

The system must define when proactive behavior is timely, premature, excessive, delayed, or invalid.

Minimum requirement:

- timing logic is explicit
- proactive action does not rely on uncontrolled intuition alone
- the system can distinguish helpful timing from intrusive timing

This means the system must not only know whether it may intervene, but whether it may intervene **at that moment** under valid interaction conditions.

Step 5 — Define Behavioral Intensity Conditions

The system must define how strong proactive intervention may become.

Minimum requirement:

- intervention intensity is explicit
-

- proactive action does not silently escalate from suggestion to control
- behavioral influence remains bounded by interaction-governance conditions

This includes regulation of:

- urgency
- repetition
- persistence
- interruption force
- escalation tone
- directive strength
- behavioral pacing impact

Step 6 — Preserve Proactive Interaction Traceability

The system must preserve traceability of proactive intervention events and escalation transitions.

Minimum requirement:

- proactive interaction events are reviewable
- intervention conditions remain reconstructable
- later audit can determine why the system entered, how it acted, and whether its behavior remained within
- governed scope

If proactive intervention cannot be reconstructed, proactive authority becomes another opaque behavioral layer.

Step 7 — Restrict Invalid Proactive Behavior

The system must not be treated as valid if proactive participation is hidden, excessive, structurally unbounded, behaviorally manipulative, or unsupported by explicit entry and boundary logic.

Minimum requirement:

- invalid proactive conditions are identifiable
- undeclared behavioral entry is excluded
- proactive intervention without governed timing, scope, and intensity is blocked, bounded, or invalidated where
- required

Scenario

A realtime assistant remains present during a live task and may proactively warn, interrupt, or redirect the user when safety-relevant conditions emerge.

Application

PIGM is used to ensure:

- proactive entry conditions are explicit
- intervention occurs only under valid thresholds
- warning intensity remains bounded
- proactive behavior does not silently exceed its safety-governance purpose

Result

The system gains a stronger proactive interaction architecture in which intervention remains helpful, timely, and governable rather than intrusive or behaviorally uncontrolled.

Scenario

An AI system participates continuously inside a collaborative environment and may proactively suggest actions, enter discussion, or redirect live workflows.

Application

PIGM is used to ensure:

- proactive participation does not begin arbitrarily
- timing and scope of interaction entry remain governed
- intervention intensity remains bounded
- later review can reconstruct when and why the system acted proactively

Result

The environment gains a stronger continuous interaction structure in which proactive participation remains bounded, visible, and compatible with live human and system collaboration.

Canonical Closing Statement

If proactive interaction cannot remain bounded by explicit entry, timing, scope, and intensity conditions, it becomes uncontrolled participation rather than governed assistance.
