

RPIM — Realtime Presence Integrity Module

Parent Standard: Continuous Interaction Layer

Category: AI & Interpretation

Subcategory: Realtime Presence Integrity

Type: Continuous Interaction Module

Version: 1.0

Status: Canonical · Open Module

Effective Date: 12 May 2026

Compatibility: OOF Methodology OS · Continuous Interaction Layer · CLIA · RIS · OGL · EVIP · AIL · Autonomous Runtime Systems · Realtime AI Architectures

Authority: OOF

Protection: MIP — Methodological Intellectual Property

Canonical Language: English

Canonical Definition

Realtime Presence Integrity Module defines the structural conditions under which a continuously present intelligent system remains operationally visible, behaviorally bounded, runtime-identifiable, and interaction-governed while actively participating inside a live environment.

A system satisfies RPIM only if:

- active presence remains structurally identifiable
- continuous participation does not occur through hidden or ambiguous runtime states
- monitoring, listening, attention, or awareness states remain operationally visible
- presence does not silently escalate into undeclared behavioral influence
- realtime participation remains bounded by interpretable integrity conditions

A system that remains continuously active without visible presence-state integrity does not satisfy RPIM.

Module Function

RPIM defines the presence integrity layer of continuous interaction governance.

It ensures that a system does not merely remain active, but remains actively present under conditions that can still be understood, reviewed, bounded, and governed.

The module applies wherever a system may remain continuously present through:

- live monitoring
- passive listening
- multimodal awareness
- continuous observation

- ambient participation
- runtime attention persistence
- environmental presence
- live human-AI interaction

Its function is not to create presence.

Its function is to ensure that presence remains structurally valid while it exists.

Step 1 — Define the Presence Object

The organization must define what exactly remains present during runtime interaction.

Minimum requirement:

- the presence object is explicit
- the active participation target is structurally bounded
- undefined presence targets are excluded from valid governance logic

The presence object may be a:

- AI assistant
 - multimodal system
 - robotic interaction entity
 - ambient monitoring system
 - continuous interpretation environment
 - live orchestration participant
 - autonomous interaction component
-

Step 2 — Define Presence States

The system must define which runtime states count as presence-relevant states.

Minimum requirement:

- presence states are explicit
- the difference between inactive, passive, monitoring, attentive, interpretive, and active participation states is identifiable
- continuous activity does not remain hidden behind vague runtime terminology

Presence states may include:

- inactive
 - passive standby
 - listening-active
 - monitoring-active
 - interpretation-active
 - intervention-ready
-

- actively participating
- escalated presence

Step 3 — Define Presence Visibility Conditions

The system must define how active presence remains operationally visible.

Minimum requirement:

- visibility conditions are explicit
- users or governed environments can distinguish passive possibility from active presence
- hidden participation states are excluded from valid presence integrity logic

This means the system must not silently remain active in ways that affect interaction while appearing inactive, absent, or neutral.

Step 4 — Define Presence Integrity Boundaries

The system must define the boundaries within which presence remains valid.

Minimum requirement:

- presence boundaries are explicit
- presence cannot silently expand across contexts, environments, or modalities without governed state transition
- active presence does not become structurally indefinite by default

Presence boundaries may include:

- environment
- modality
- time
- interaction scope
- attention scope
- monitoring scope
- escalation threshold
- intervention readiness

Step 5 — Define Presence Escalation Conditions

The system must define when presence intensifies from passive availability into active interpretive or behavioral participation.

Minimum requirement:

- escalation conditions are explicit
- active presence does not intensify without governed transition logic
- changes from listening to interpretation, from interpretation to intervention, or from observation to participation
- remain identifiable

- This prevents silent escalation of presence authority.

Step 6 — Preserve Presence Traceability

The system must preserve traceability of presence-state changes and active presence periods.

Minimum requirement:

- presence-state changes are reviewable
- active participation periods remain reconstructable
- later audit can determine when presence began, how it changed, and under which runtime conditions it remained
- active

If presence cannot be reconstructed, presence integrity becomes another opaque claim.

Step 7 — Restrict Invalid Presence Design

The system must not be treated as valid if presence remains hidden, ambiguous, structurally unbounded, or behaviorally active without visible runtime integrity conditions.

Minimum requirement:

- invalid presence conditions are identifiable
- hidden continuous participation is excluded
- structurally undefined active presence is blocked, bounded, or invalidated where governance requires visibility

Scenario

A continuous voice assistant remains available inside a live environment and may listen, interpret, and react across ongoing interaction time.

Application

RPIM is used to ensure:

- active listening and monitoring states are visible
- passive availability is distinguishable from active presence
- escalation from listening to active interpretation remains governed
- continuous presence does not become hidden behavioral participation

Result

The system gains a stronger presence architecture in which continuous availability remains operationally visible and structurally governable.

Scenario

A multimodal system remains continuously present inside an environment through sensors, audio streams, contextual signals, and live interpretation pathways.

Application

RPIM is used to ensure:

- continuous presence states are explicitly defined
 - monitoring and interpretive activation remain distinguishable
 - active presence does not silently exceed bounded scope
 - later review can reconstruct when and how the system remained operationally present
-

Result

The environment gains a stronger realtime interaction architecture in which continuous system presence remains bounded, visible, and integrity-compatible.

Canonical Closing Statement

If continuous presence cannot remain visible, bounded, and traceable during runtime, it becomes hidden participation rather than governed interaction.
