

Example Architectures

Core Statement

OOF® Governance Architecture is modular.

This means operational governance structures may be composed differently depending on the type of system, the source of risk, the level of autonomy, and the conditions under which validity must be preserved.

The examples below do not describe fixed products.

They show how OOF® standards, modules, and layers may be combined into coherent governance architectures for different operational realities.

Example 1 — Autonomous Agent Runtime Architecture

This architecture applies to environments where AI agents operate with live runtime exposure, decision pathways, tool access, and execution consequences.

It may include:

- RIS for runtime integrity
- ARIV™ for controlled AI execution boundaries
- ART for audit in real time
- OIB™ for organizational information boundary control
- runtime escalation logic
- human override structures

Purpose

To ensure that autonomous agent behavior remains bounded, auditable, escalation-capable, and structurally governable during live operation.

Governance Outcome

The system is no longer governed as a loose AI workflow. It becomes a runtime-controlled operational environment.

Example 2 — Cognitive Simulation Governance Architecture

This architecture applies to environments where simulation is used to test cognition, escalation, interaction, memory influence, or multi-agent behavior before real-world reliance.

It may include:

- SIMULOS® as the parent simulation standard
 - CSM — Cognitive Simulation Module
 - REM — Runtime Escalation Module
 - MISIM — Memory Integrity Simulation Module
 - MACSM — Multi-Agent Coordination Simulation Module
 - interpretation boundary logic through CLIA®
-

Purpose

To ensure that simulation does not operate as synthetic approximation only, but as a structurally valid pre-operational reality layer.

Governance Outcome

The organization gains a simulation environment that supports real reliance instead of appearance-based confidence.

Example 3 — Human–AI Safety Architecture

This architecture applies where AI systems, robotics, or embodied systems interact directly with people under conditions where ambiguity, escalation failure, or unstable behavior would create safety or liability risk.

It may include:

- **SIMULOS®**
- **HISM** — Human Interaction Safety Module
- **RIS**
- **INTEGROS®**
 - human override logic
 - escalation and intervention pathways
 - runtime verification structures

Purpose

To ensure that human-facing system behavior is tested, bounded, and governable before broader exposure.

Governance Outcome

The system is no longer trusted because it appears acceptable.
It is trusted only when human interaction conditions remain structurally valid.

Example 4 — Enterprise Information Integrity Architecture

This architecture applies to organizations where internal information, documents, emails, outputs, and AI-assisted workflows must remain within defined release and traceability conditions.

It may include:

- **OIB™** — Organizational Information Boundary Module
- **ART**
- **ECM** — Event Capture Module
- **OVM** — Output Verification Module
- **ARIM** — Audit Record Integrity Module
- release and accountability logic

Purpose

To preserve the integrity of internal information movement and prevent uncontrolled externalization through humans, AI systems, or process fragmentation.

Governance Outcome

The organization gains a real governance boundary around internal information instead

of relying only on policy, trust, or isolated technical controls.

Example 5 — Real-Time Audit Architecture

This architecture applies where trust depends on verifying events, states, outputs, and escalation conditions while they still exist as operational reality.

It may include:

- **ART** — Audit in Real Time Standard
- **ECM** — Event Capture Module
- **SVM** — State Verification Module
- **OVM** — Output Verification Module
- **ARIM** — Audit Record Integrity Module
- **AEM** — Audit Escalation Module

Purpose

To transform audit from delayed review into a live verification layer linked directly to operational conditions.

Governance Outcome

Audit becomes reality-linked, state-linked, and structurally stronger than retrospective reporting models.

Example 6 — Multi-Layer High-Risk Operational Architecture

This architecture applies to high-risk environments where runtime behavior, information movement, simulation reliance, audit, and human interaction all intersect.

It may include:

- **RIS**
- **INTEGROS®**
- **ART**
- **SIMULOS®**
- **OIB™**
- memory governance
- escalation structures
- human override logic
- validation and truth-layer alignment through **TVL®**

Purpose

To govern operational environments in which no single standard is sufficient and multiple live governance conditions must remain aligned simultaneously.

Governance Outcome

The system becomes governable as a complete operational architecture rather than as disconnected controls.

What These Examples Show

These examples show that OOF® Governance Architecture does not begin with a fixed package.

It begins with:

- operational reality
- governance need
- structural risk
- required validity conditions

From there, architecture is composed through compatible standards, modules, and layers.

This means different clients, systems, and environments may require different architectures while still operating under the same OOF® methodological logic.

Why This Matters

Without examples, Governance Architecture may appear abstract.

With examples, it becomes clear that OOF® can structure:

- runtime environments
- simulation systems
- information boundaries
- live audit layers
- human–AI safety conditions
- high-risk operational systems

This is where modular architecture becomes practical.

System Principle

A governance architecture is not defined by the number of components it contains.

It is defined by whether the selected components are sufficient, compatible, and structurally aligned for the operational reality they are meant to govern.

Final Statement

OOF® Governance Architecture does not apply one model to every system.

It composes the right governance structure for the right operational reality.

Example architectures show that OOF® standards and modules are not isolated texts.

They are building blocks of real operational governance systems.
