

ICM — Initial Commitment Module

Parent Standard: Transparency & Probabilistic Integrity Standard

Methodology Sign: Fair Win Model™ (FWM™)

Category: Governance & Enforcement

Subcategory: Initial Commitment Integrity

Type: Probabilistic Integrity Module

Version: 1.0

Status: Canonical · Open Module

Effective Date: 9 May 2026

Compatibility: OOF® Methodology OS™ · Transparency & Probabilistic Integrity Standard · TVL® ·

INTEGROS® · ArtData® · UCL™

Authority: OOF®

Protection: MIP® — Methodological Intellectual Property

Canonical Language: English (UCL™)

Canonical Definition

Initial Commitment Module defines the structural conditions under which the initial prize, reward, or probabilistic allocation state of a system is committed in a traceable, immutable, and auditor-verifiable form before operational launch.

A system satisfies ICM only if:

- the initial committed state is explicitly defined before activation
- prize or reward inventory is structurally identifiable
- issuance volume and distribution structure are fixed or governably declared
- the commitment remains timestamped, traceable, and resistant to silent alteration
- lifecycle reality can be measured against the committed starting state

A system that operates without a verifiable initial commitment does not satisfy ICM.

Module Function

ICM defines the starting-state integrity layer of probabilistic transparency.

It ensures that a probabilistic system does not begin from an unverifiable claim, but from a committed reference state against which later distribution, redemption, remaining-state computation, and disclosure may be audited.

The module applies wherever prize-based, reward-based, or randomized systems require a trustworthy initial state.

Minimum Implementation Framework (MIF)

Step 1 — Define the Initial Reward State

The organization must define the initial prize or reward inventory before system activation.

Minimum requirement:

- reward tiers are explicit
- committed quantities are identifiable
- undefined initial inventory is excluded from valid operation

Step 2 — Define Distribution Structure

The system must define the initial distribution logic associated with the committed state.

Minimum requirement:

- allocation structure is explicit
- issuance volume is defined
- structurally undefined distribution starting conditions are excluded

Step 3 — Define Commitment Form

The system must define how the initial state is committed.

Minimum requirement:

- commitment form is timestamped
- commitment form is traceable
- commitment form is resistant to silent modification

Step 4 — Define Verification Conditions

The system must define how the initial commitment may later be verified.

Minimum requirement:

- the committed state is auditor-verifiable
- later lifecycle records can be compared against the initial state
- unverifiable initial commitment is excluded from valid transparency logic

Step 5 — Preserve Commitment Integrity

The system must preserve the integrity of the committed starting state throughout lifecycle use.

Minimum requirement:

- the initial state remains stable as a reference point
- later changes do not silently rewrite the starting state
- commitment integrity remains structurally reviewable

Step 6 — Restrict Invalid Activation

The system must not be treated as valid if it becomes operational without a defined, traceable, and verifiable initial commitment.

Minimum requirement:

- invalid starting-state conditions are identifiable
- launch without commitment is blocked or invalidated
- probabilistic operation does not begin from uncommitted reality

Use Case 1 — Instant Lottery Launch

Scenario

A lottery operator launches a prize-based system and must prove the original quantity, tier structure, and committed state of all rewards before public participation begins.

Application

ICM is used to ensure:

- the initial reward inventory is explicit
- the distribution structure is committed before activation
- the starting state is timestamped and verifiable
- future lifecycle transparency can be measured against the original committed reality

Result

The operator gains a trustworthy starting reference for later auditability, remaining-state computation, and disclosure integrity.

Use Case 2 — Digital Reward Allocation Platform

Scenario

A digital or tokenized reward platform launches a randomized allocation structure in which future trust depends on proving the original reward pool and committed issuance logic.

Application

ICM is used to ensure:

- the initial probabilistic reward state is committed before operation
 - allocation structure is explicitly defined
 - the commitment remains traceable and reviewable
 - later transparency claims remain anchored to a stable starting point
-

Result

The platform gains a structurally governed starting-state layer instead of relying on unverified launch claims.

Canonical Closing Statement

If the starting state is not committed before launch, lifecycle fairness cannot be structurally verified.
