Canonical Definition

Execution Traceability Transition Module defines the structural conditions under which the transition from internal decision, runtime process, or **contained execution** into external action, released output, or operational consequence remains fully traceable, attributable, and reconstructable.

A system satisfies ETTM only if:

- the transition from decision to execution is explicitly traceable
- the transition from execution to external effect is explicitly traceable
- the origin, path, and consequence of transition remain reconstructable
- no silent gap exists between **contained execution** and operational effect
- execution does not cross into consequence through opaque, detached, or non-attributable transition paths

A system that cannot trace the transition from internal execution to external consequence does not satisfy ETTM.

Module Function

ETTM defines the transition-traceability layer of execution containment.

It ensures that **contained execution** does not lose accountability at the critical point where internal activity becomes external effect.

The module applies wherever systems move from:

- internal decision to action
- runtime process to released output
- **contained execution** to operational consequence
- generated result to external impact

- bounded environment to real-world effect
-

Minimum Implementation Framework (MIF)

Step 1 — Define Transition Points

The organization must define where execution transitions into external consequence.

Minimum requirement:

- transition points are explicit
 - internal and external phases are distinguishable
 - undefined transition boundaries are excluded from valid operation
-

Step 2 — Define Origin Linkage

The system must define how external effect remains linked to originating execution.

Minimum requirement:

- origin linkage is explicit
 - source decision, runtime event, or execution path is attributable
 - detached consequence is excluded from valid transition logic
-

Step 3 — Define Transition Path

The system must define through which path execution becomes external effect.

Minimum requirement:

- transition pathway is explicit
 - intermediate stages are identifiable
 - hidden or silent transition paths are excluded from valid containment
-

Step 4 — Define Consequence Attribution

The system must define how the resulting external effect is attributed back to execution.

Minimum requirement:

- consequence attribution is explicit
 - output, action, or effect is not treated as independent from execution source
 - unbound consequence is excluded from valid operation
-

Step 5 — Preserve Transition Traceability

The system must preserve visibility of what crossed the boundary, when it crossed, why it crossed, and under which condition.

Minimum requirement:

- transition events are traceable
- later review can reconstruct the full path from execution to consequence
- transition does not become opaque after operational effect occurs

Step 6 — Restrict Invalid Transition

The system must not be treated as valid if execution produces external consequence through untraceable, detached, or structurally hidden transition paths.

Minimum requirement:

- invalid transition conditions are identifiable
- non-attributable transition is blocked or invalidated
- external effect alone does not justify missing transition traceability

Use Case 1 — AI Agent Moving from Draft to External Action

Scenario

An AI agent generates internal outputs, drafts, or execution candidates inside a contained environment, and one of them later becomes an external message, released file, or triggered action.

Application

ETTM is used to ensure:

- the transition point is explicit
- the released consequence remains linked to originating execution
- intermediate steps are traceable
- no opaque jump occurs between internal generation and external release

Result

The organization gains a stronger basis for proving how **contained execution** became external effect and under which governed transition

path that happened.

Use Case 2 — Enterprise Runtime Triggering Operational Consequence

Scenario

A runtime system processes internal execution steps and then creates an external operational effect such as a workflow trigger, file write, approval action, or downstream system event.

Application

ETTM is used to ensure:

- transition boundaries are governed
 - origin linkage remains preserved
 - consequence attribution remains reconstructable
 - operational effect does not occur through silent transition loss
-

Result

The organization gains a structurally governed traceability bridge between **contained execution** and real operational consequence.

Canonical Closing Statement

If execution crosses into consequence without traceable transition, execution containment has not been achieved.
