

PSIM — Prioritization Stability Integrity Module

OOF™ Origin Open Foundation™

Independent Methodological Authority

Modul2 PSIM — Prioritization Stability Integrity Module

Category: Governance & Enforcement

Parent Standard: Operational Cognitive Load Governance Standard (OCLGS)

Architecture Ecosystem: Structured Reality Standards™

Architecture Family: Operational Reality Standards™

Operational Layer: Cognition Governance Layer

Governed Space: Prioritization Stability

Subcategory: Prioritization Stability Integrity

Type: Operational Cognitive Load Governance Module

Version: 1.0

Status: Canonical · Open Module

Effective Date: 19 May 2026

Compatibility: OOF Methodology OS · Operational Cognitive Load Governance Standard (OCLGS) · Operational Attention Governance Standard (OAGS) · Operational Decision Integrity Standard (ODIS) · Runtime Integrity Standard (RIS) · Operational Escalation Integrity Standard (OESIS) · Operational Evidence & Auditability Standard (OEAS) · INTEGROS® — Integrity Standard · Autonomous Runtime Systems · Multi-Agent Coordination Environments

Authority: OOF

Protection: MIP — Methodological Intellectual Property

Canonical Language: English (UCL)

Canonical Definition

Prioritization Stability Integrity Module (PSIM) defines the structural conditions under which runtime operational prioritization, adaptive task prioritization continuity, distributed prioritization coherence, and consequence-bearing prioritization states remain materially stable, traceable, and operationally governable across autonomous runtime environments.

A system satisfies PSIM only if:

- runtime operational prioritization remains materially stable
- adaptive prioritization continuity preserves governance-valid cognitive stability
- distributed prioritization coherence remains operationally aligned
- consequence-bearing prioritization continuity remains traceable
- prioritization fragmentation does not destabilize operational legitimacy
- A system that preserves runtime execution while operational prioritization materially destabilizes does not satisfy PSIM.

Module Operational Role

PSIM defines the prioritization stability layer of OCLGS by preserving governance-valid runtime prioritization continuity across autonomous operational environments.

Module Operational Space

PSIM governs the prioritization stability space of OCLGS by preserving adaptive task prioritization continuity, distributed prioritization coherence, runtime cognitive stability, and consequence-bearing operational prioritization across runtime systems.

Module Function

- The module applies wherever systems must preserve:
- runtime operational prioritization
- adaptive prioritization continuity
- distributed prioritization coherence
- operational cognitive stability
- consequence-bearing prioritization continuity
- governance-valid cognitive alignment
- Its function is to ensure that operational prioritization remains materially stable strongly enough to preserve governancevalid runtime cognition across autonomous runtime environments.

Minimum Implementation Framework

1. Define the Prioritization Stability Object

The organization must define which prioritization structures require governance preservation. This may include: runtime task-prioritization systems orchestration prioritization infrastructures distributed cognitive-priority environments adaptive execution prioritization multi-agent operational prioritization consequence-bearing prioritization pathways operational-critical prioritization systems

2. Define Prioritization Stability Conditions

The system must define the conditions under which runtime prioritization remains materially stable and operationally aligned. This includes: adaptive prioritization continuity distributed prioritization coherence runtime cognitive stability operational-priority legitimacy governance-valid prioritization continuity

3. Define Prioritization Fragmentation Detection Logic

The system must define how materially unstable prioritization or prioritization fragmentation is identified. This may include: prioritization overload drift orchestration-priority instability distributed prioritization divergence runtime task-collapse conditions consequence-bearing prioritization mismatch

4. Define Operational Response or Governance Logic

The system must define governance logic for materially unstable prioritization conditions. Governance response may include:
prioritization stabilization orchestration-priority correction
distributed prioritization synchronization runtime task reconstruction
operational review activation operational invalidation where required

5. Preserve Traceability & Restrict Invalid Conditions

The system must preserve reconstructable traceability of prioritization continuity and prioritization-fragmentation states. A system must not remain cognition-valid if runtime operational prioritization materially destabilizes while systems continue assuming governance-valid cognitive coherence remains preserved.

Use Case 1 — Autonomous AI Coordination

Infrastructure

Scenario

A distributed AI infrastructure continuously coordinates adaptive operational execution across orchestration systems and autonomous runtime environments.

Application

PSIM preserves governance-valid prioritization continuity through orchestration-priority governance and distributed prioritization stabilization.

Result

The organization gains stronger operational prioritization coherence and reduced hidden prioritization fragmentation across autonomous runtime systems.

Use Case 2 — Enterprise Realtime Decision

Environment

Scenario

A persistent operational infrastructure continuously performs realtime coordination across distributed autonomous systems and adaptive runtime environments.

Application

PSIM preserves governance-valid operational prioritization through adaptive task-governance and distributed cognitivepriority

synchronization.

Result

The environment gains stronger runtime prioritization stability and reduced operational overload instability across autonomous operational ecosystems.

Canonical Closing Statement

If runtime operational prioritization cannot remain materially stable across autonomous runtime environments, systems may preserve operational execution while governance-valid cognitive coherence progressively destabilizes across distributed prioritization layers.
