

About Operational Decision Integrity Standard - (ODIS)

Canonical Definition

Operational Decision Integrity Standard (ODIS) defines the structural conditions under which runtime operational decisions, adaptive decision evolution, distributed decision coordination, and consequence-bearing decision states remain materially stable, traceable, governable, and operationally aligned. Operational validity is not determined only by execution. It also depends on whether runtime decisions themselves remain valid.

What This Standard Is

ODIS is a parent standard defining the governance architecture for operational decision integrity.

It governs:

- runtime decision validity
 - decision traceability
 - adaptive decision stability
 - consequence-bearing decision governance
 - authority-aligned decision conditions
 - distributed decision coordination
-

What This Standard Is Not

ODIS is not a decision engine, optimization tool, ranking model, workflow automation system, or AI output evaluator. It does not govern decision technology alone. It governs whether operational decisions remain valid, traceable, and governable during runtime.

Why This Standard Exists

Future AI systems will not only execute tasks. They will increasingly make runtime decisions. A system may perceive correctly, prioritize correctly, and still make an invalid decision. This creates risks such as decision drift, authority-invalid decisions, consequence misalignment, escalation corruption, and distributed decision fragmentation. ODIS exists because runtime decisions become a governance condition in autonomous operational systems.

Core Insight

A system is not operationally valid merely because it produces an output. It becomes valid only when the decision behind that output remains governable.

Operational Architecture Space

ODIS defines the operational architecture space for decision integrity, runtime decision governance, decision traceability, adaptive decision stability, consequence-bearing

decisions, and authority-aligned decision validity.

Use Case 1 — Autonomous AI Decision System

Scenario

An AI system makes runtime decisions across delegated workflows and autonomous execution environments.

Application

ODIS preserves decision traceability, authority alignment, and consequence-bearing decision validity.

Result

The organization gains stronger decision governance and reduced hidden decision drift.

Use Case 2 — Robotics Runtime Decision Layer

Scenario

A robotics system selects operational actions during changing runtime conditions.

Application

ODIS governs whether runtime decisions remain aligned with context, authority, perception, and operational consequence.

Result

The environment gains stronger operational safety and reduced invalid autonomous decision behavior.

Architectural Position

Within the OOF system, ODIS belongs under:

- Governance & Enforcement
- Operational Decision Integrity Architecture

It extends the cognition governance stack beyond execution, context, memory, intent, attention, and perception into runtime decision validity.

Closing Definition

Operational decisions are not valid merely because systems act. Operational decisions become valid only when decision formation, authority alignment, consequence logic, and runtime traceability remain materially governable.
