

Operational Decision Integrity Standard - (ODIS)

OriginID: OOF-OID-GOV-ODIS-2026-05-19-0001

Category: Governance & Enforcement

Subcategory: Operational Decision Integrity Architecture

Type: Parent Standard

Version: 1.0

Status: Canonical · Open Standard

Effective Date: 19 May 2026

Compatibility: OOF Methodology OS · Runtime Integrity Standard (RIS) · Operational Context Integrity Standard (OCIS) · Operational Memory Integrity Standard (OMIS) · Operational Intent Integrity Standard (OIIS) · Operational Attention Governance Standard (OAGS) · Operational Perception Integrity Standard (OPIS) · Operational Evidence & Auditability Standard (OEAS) · Authority & Accountability Layer Standard (AALS) · Semantic Integrity Standard (SEIS) · Cognitive Efficiency Economy Standard (CEES) · INTEGROS® — Integrity Standard · Multi-Layer Truth Validation Framework (MTVF) · Ethical Virtual Integrity Protocol (EVIP)

AI-Readable: Yes

Authority: OOF

Protection: MIP — Methodological Intellectual Property

Canonical Language: English (UCL)

Canonical Definition System

Canonical Definition

Operational Decision Integrity Standard (ODIS) defines the structural conditions under which runtime operational decisions, adaptive decision evolution, distributed decision coordination, consequence-bearing decision states, and autonomous decision execution remain materially stable, traceable, governable, and operationally aligned across live execution environments and autonomous operational systems.

Operational validity is not determined only by execution continuity, contextual alignment, memory continuity, intent persistence, attention stability, or perception integrity.

Operational validity increasingly depends on whether systems produce materially governable decisions during runtime operation.

ODIS therefore governs not only what systems execute, perceive, remember, intend, prioritize, or monitor, but also how systems operationally decide across live runtime environments.

A. Standard Abstract

Future operational systems increasingly operate through:

- autonomous runtime decisions
- adaptive operational prioritization
- distributed decision coordination
- escalation-sensitive decision pathways
- realtime operational judgment
- AI-assisted decision systems
- orchestration-level decision routing
- persistent runtime decision evolution
- consequence-bearing decision execution

Yet most operational systems still treat decision-making primarily as:

- output generation
- optimization selection
- model inference
- ranking logic
- probability weighting
- operational automation

This creates a major governance problem.

A system may:

- preserve runtime execution
- maintain contextual continuity
- preserve operational memory
- maintain operational intent
- preserve operational attention
- maintain operational perception

while operational decisions underneath become:

- consequence-diverged
- escalation-corrupted
- operationally unstable
- contextually misaligned
- authority-invalid
- traceability-degraded
- decision-drifted

A system may therefore remain operationally active while runtime decision validity has already materially destabilized.

ODIS exists to govern that condition.

B. Core Principle

Operational decisions are not valid merely because systems produce outputs or execute actions. Operational decisions become operationally valid only when runtime decision continuity, consequence-bearing alignment, operational traceability, and governance-valid decision conditions remain materially preservable across execution environments.

C. Scope

This standard may apply to:

- AI agent systems
- autonomous runtime systems
- robotics infrastructures
- orchestration environments
- enterprise AI systems
- distributed cognition systems
- escalation-sensitive infrastructures
- realtime monitoring systems
- adaptive operational environments
- autonomous industrial systems
- multi-agent coordination systems
- consequence-bearing runtime environments

ODIS applies wherever operational validity depends on how systems produce runtime operational decisions.

D. Why This Standard Exists

Most operational systems still evaluate:

- execution outputs
- operational completion
- runtime responsiveness
- model accuracy
- computational efficiency

But future operational systems increasingly depend on:

- operational decision integrity across runtime environments.

Operational instability increasingly emerges through:

- decision drift
- escalation corruption
- authority-invalid decisions
- consequence-bearing decision instability
- distributed decision fragmentation
- contextually misaligned decisions
- operationally unjustified actions
- adaptive decision corruption

A system may preserve:

- runtime activity
- operational execution
- orchestration continuity
- attention allocation
- perception continuity
- while operational decision validity underneath has already degraded materially.

This creates decision-governed operational risk.

ODIS exists because future governance increasingly requires operational decisions themselves to remain governable.

E. Operational Decision Logic

Operational decision integrity exists only when the following remain materially preservable:

1. Decision Continuity Integrity

Operational decisions remain materially stable across runtime evolution.

2. Consequence-Bearing Decision Integrity

Decisions affecting real operational outcomes remain materially governable.

3. Decision Traceability Integrity

Operational decisions remain materially reconstructable and reviewable.

4. Adaptive Decision Stability

Adaptive runtime decision evolution does not materially destabilize operational alignment.

5. Authority-Aligned Decision Integrity

Operational decisions remain materially aligned with governance-valid authority conditions.
If these layers degrade materially, systems may preserve runtime execution while operational decision validity underneath becomes operationally unstable.

F. Operational Architecture Space

ODIS defines the operational architecture space for:

- operational decision governance
- runtime decision integrity
- consequence-bearing decision continuity
- distributed decision coordination
- adaptive decision stability
- authority-aligned decision governance
- operational decision traceability
- escalation-sensitive decision continuity
- autonomous runtime decision governance

This space exists because future operational systems increasingly require governance not

only of execution itself, but of runtime decision legitimacy across operational environments.

G. Difference Between Attention, Perception, and Decision

Operational attention, perception, and decision are related but structurally distinct governance layers.

Operational attention governs:

- runtime prioritization
- signal relevance allocation
- escalation sensitivity
- operational focus continuity

Operational perception governs:

- runtime sensory interpretation
- operational reality recognition
- multimodal perception continuity
- perception-reality alignment

Operational decision governs:

- runtime operational choice formation
- consequence-bearing action selection
- operational judgment continuity
- decision legitimacy
- governance-valid action determination

A system may preserve operational attention and operational perception continuity while operational decisions underneath materially destabilize.

ODIS therefore governs runtime operational decision validity itself.

H. Runtime Position

ODIS operates directly alongside runtime operational systems but is not identical to execution, context, memory, intent, attention, or perception governance.

Runtime

Integrity Standard (RIS) governs whether execution remains operationally valid.

Operational Context Integrity Standard (OCIS) governs whether execution remains contextually aligned.

Operational Memory Integrity Standard (OMIS) governs whether operational memory continuity remains valid across time.

Operational Intent Integrity

Standard (OIIS) governs whether operational intent continuity remains valid across execution evolution.

Operational Attention Governance Standard (OAGS) governs whether runtime prioritization remains operationally aligned.

Operational Perception Integrity

Standard (OPIS) governs whether runtime operational perception remains materially aligned with operational reality.

Operational Decision Integrity Standard (ODIS) governs whether runtime operational decisions themselves remain materially governable across operational environments.

This distinction becomes critical in:

- autonomous systems
 - robotics infrastructures
 - AI agents
 - orchestration systems
 - distributed cognition environments
 - escalation-sensitive operational ecosystems
-

I. Decision Drift Rule

Decision drift occurs when operational decision formation progressively diverges away from materially governable operational conditions while systems continue assuming runtime decision legitimacy remains preserved.

This may include:

- consequence-bearing misalignment
- escalation corruption
- authority-invalid decisions
- distributed decision fragmentation
- operationally unjustified actions
- adaptive decision instability
- contextual decision divergence
- runtime decision degradation

A system may continue operating while operational decision validity underneath has already destabilized materially.

ODIS exists to expose and govern that condition.

J. Validity Logic

A system is valid under ODIS when:

- operational decisions remain materially stable
-

- consequence-bearing decisions preserve operational alignment
- runtime decision traceability remains reconstructable
- adaptive decision evolution remains materially governable
- authority-aligned decision conditions remain operationally valid
- distributed decision coordination preserves operational continuity
- runtime operational decision legitimacy remains materially traceable

A system becomes invalid under ODIS when:

- operational decisions materially destabilize
- consequence-bearing decision continuity diverges
- decision traceability materially degrades
- adaptive decision evolution corrupts operational alignment
- authority-invalid decisions emerge materially
- distributed runtime decision coordination destabilizes
- systems preserve runtime execution while operational decision legitimacy
- underneath destabilizes

K. Relationship to Other OOF Standards

ODIS operates naturally with:

- Runtime Integrity Standard (RIS)
- Operational Context Integrity Standard (OCIS)
- Operational Memory Integrity Standard (OMIS)
- Operational Intent Integrity Standard (OIIS)
- Operational Attention Governance Standard (OAGS)
- Operational Perception Integrity Standard (OPIS)
- Operational Evidence & Auditability Standard (OEAS)
- Authority & Accountability Layer Standard (AALS)
- Semantic Integrity Standard (SEIS)
- Cognitive Efficiency Economy Standard (CEES)
- INTEGROS® — Integrity Standard
- Multi-Layer Truth Validation Framework (MTVF)
- Ethical Virtual Integrity Protocol (EVIP)

ODIS does not replace these standards.

It governs the runtime operational decision layer through which operational actions become materially legitimized across operational systems.

L. Foundational Principle

If operational decisions cannot remain materially governable across runtime environments, systems may preserve operational execution while operational legitimacy progressively diverges from runtime reality.

Canonical Closing Statement

Operational Decision Integrity Standard (ODIS) defines the structural conditions under which runtime operational decisions, adaptive decision evolution, distributed decision coordination, consequence-bearing decision states, and autonomous decision execution remain materially stable, traceable, governable, and operationally aligned across live execution environments and autonomous operational systems. Operational systems are not valid merely because they execute actions or produce outputs.

Operational validity

increasingly depends on whether runtime operational decisions themselves remain materially governable across execution environments.
