

SORIM — Shared Operational Reality Integrity Module

Parent Standard: Operational Reality Synchronization Standard (ORSS)

Category: Governance & Enforcement

Subcategory: Shared Operational Reality Integrity

Type: Operational Reality Synchronization Module

Version: 1.0

Status: Canonical · Open Module

Effective Date: 19 May 2026

Compatibility: OOF Methodology OS · Operational Reality Synchronization Standard (ORSS) · Operational Context Integrity Standard (OCIS) · Operational Perception Integrity Standard (OPIS) · Operational Evidence & Auditability Standard (OEAS) · INTEGROS® — Integrity Standard · Distributed Runtime Systems · Multi-Agent Infrastructures

Authority: OOF

Protection: MIP — Methodological Intellectual Property

Canonical Language: English (UCL)

Canonical Definition

Shared Operational Reality Integrity Module (SORIM) defines the structural conditions under which shared operational reality states, distributed runtime coherence, multi-agent operational alignment, and consequence-bearing operational- state continuity remain materially stable, traceable, and operationally governable across distributed operational environments.

A system satisfies SORIM only if:

- shared operational reality remains materially coherent
- distributed runtime alignment preserves operational continuity
- multi-agent operational-state synchronization remains stable
- consequence-bearing operational states remain traceable
- operational-reality divergence does not destabilize runtime coherence

A system that preserves runtime execution while shared operational reality materially diverges does not satisfy SORIM.

Module Operational Role

SORIM defines the shared operational reality layer of ORSS by preserving governance-valid distributed operational coherence across runtime environments.

Module Operational Space

SORIM governs the shared operational reality space of ORSS by preserving distributed operational-state continuity, multi- agent alignment coherence, realtime operational synchronization, and consequence-bearing runtime coherence across distributed systems.

Module Function

The module applies wherever systems must preserve:

- shared operational reality continuity
- distributed runtime coherence
- multi-agent operational alignment
- realtime operational synchronization
- consequence-bearing operational-state stability
- governance-valid runtime coherence

Its function is to ensure that shared operational reality remains materially coherent strongly enough to preserve synchronized runtime operational continuity across distributed environments.

Minimum Implementation Framework

1. Define the Shared Operational Reality Object

The organization must define which distributed operational-state structures require governance preservation.

This may include:

- shared runtime operational states
 - distributed orchestration environments
 - multi-agent coordination systems
 - realtime operational synchronization layers
 - adaptive runtime coordination
 - consequence-bearing distributed operations
 - operational-critical coordination infrastructures
-

2. Define Shared Operational Reality Conditions

The system must define the conditions under which shared operational reality remains materially stable and operationally aligned.

This includes:

- distributed runtime coherence
 - operational-state synchronization continuity
 - multi-agent alignment stability
 - realtime coordination persistence
 - governance-valid shared operational continuity
-

3. Define Operational Reality Divergence Detection Logic

The system must define how materially unstable shared operational reality or operational-state divergence is identified.

This may include:

- distributed operational mismatch
 - orchestration-state fragmentation
 - multi-agent runtime divergence
 - realtime synchronization instability
 - consequence-bearing operational incoherence
-

4. Define Operational Response or Governance Logic

The system must define governance logic for materially unstable shared operational reality conditions.

Governance response may include:

- synchronization reconstruction
 - distributed coordination stabilization
 - operational-state reconciliation
 - adaptive synchronization restriction
 - operational review activation
 - operational invalidation where required
-

5. Preserve Traceability & Restrict Invalid Conditions

The system must preserve reconstructable traceability of shared operational-reality continuity and operational-divergence states. A system must not remain synchronization-valid if shared operational reality materially diverges while systems continue assuming distributed runtime coherence remains preserved.

Use Case 1 — Multi-Agent AI Coordination

Infrastructure

Scenario

A distributed AI infrastructure continuously coordinates runtime operational states across autonomous agents and orchestration systems.

Application

SORIM preserves governance-valid shared operational reality through distributed runtime coherence governance and multi-agent synchronization stabilization.

Result

The organization gains stronger distributed operational consistency and reduced hidden operational-reality divergence.

Use Case 2 — Autonomous Industrial

Coordination Environment

Scenario

An autonomous industrial infrastructure continuously synchronizes distributed operational states across adaptive runtime systems and realtime coordination environments.

Application

SORIM preserves governance-valid operational coherence through distributed operational-state synchronization and realtime coordination governance.

Result

The environment gains stronger shared operational continuity and reduced distributed runtime fragmentation.

Canonical Closing Statement

If shared operational reality cannot remain materially coherent across distributed runtime environments, systems may preserve operational execution while synchronized operational continuity progressively separates from distributed runtime alignment.
