

RDIM — Reality Drift Integrity Module

OOF™ Origin Open Foundation™

Independent Methodological Authority

OriginID: OOF-OID-AI-RDIM-2026-06-03-0001

Architecture Ecosystem: Structured Reality Standards™

Architecture Family: Cognitive Governance Intelligence Architecture (CLIA®)

Operational Layer: Cognitive Reality Modeling Governance Layer

Governed Space: Reality Drift Integrity

Category: AI & Interpretation

Subcategory: Reality Drift Governance

Type: Cognitive Reality Modeling Module

Parent Standard: Cognitive Reality Modeling Standard (CRMS)

Version: 1.0

Status: Canonical · Open Module

Origin Date: 3 June 2026

Compatibility: OOF Methodology OS ·
Cognitive Reality Modeling Standard (CRMS) ·
Model Alignment Integrity Module (MAIM) ·
Model Adaptation Integrity Module (MADIM) ·
Cognitive Interpretation Integrity Standard (CIIS) ·
Cognitive Reasoning Integrity Standard (CRIS) ·
Multi-Layer Truth Validation Framework (MTVF) ·
INTEGROS® — Integrity Standard

AI-Readable: Yes

Protection: MIP — Methodological Intellectual Property

Canonical Language: English (UCL)

Canonical Definition

Reality Drift Integrity Module (RDIM) defines the structural conditions under which divergence between internal reality models and observable reality remains detectable, measurable, traceable, governable, and operationally valid throughout cognition and reality-modeling processes.

RDIM governs reality drift.

The module ensures that cognition remains capable of recognizing when its internal model of reality no longer sufficiently reflects operational reality.

A system satisfies RDIM only if:

- reality drift remains detectable
- divergence remains measurable
- drift causes remain identifiable
- drift progression remains traceable

- correction opportunities remain available
- reality-model validity remains assessable

A cognition environment that cannot detect significant divergence from reality does not satisfy RDIM.

Module Operational Role

RDIM defines the reality-drift governance layer of CRMS.

Its role is to preserve awareness of divergence between reality and reality models.

Module Operational Space

RDIM governs:

- reality drift
- model divergence
- reality-model mismatch
- drift measurement
- divergence governance
- reality-validation failures
- model degradation visibility
- reality-connected cognition

The module applies wherever cognition relies on internal models to understand, predict, or navigate reality.

Module Function

The module applies wherever systems must preserve:

- drift visibility
- divergence awareness
- reality accountability
- governance-valid correction
- model reliability
- operationally valid cognition

Its function is to ensure that reality-model failures become visible before they evolve into operational failures.

Minimum Implementation Framework

1. Define the Reality Drift Object

The organization must define which forms of reality drift require governance.

This may include:

- environmental drift
 - operational drift
 - strategic drift
 - predictive drift
 - simulation drift
 - behavioral drift
 - world-model drift
-

- autonomous-agent model drift

2. Define Reality Drift Conditions

The system must define the conditions under which reality drift becomes operationally significant.

This includes:

- divergence thresholds
- measurement requirements
- validation requirements
- correction requirements
- escalation requirements
- governance-valid drift conditions

3. Define Reality Drift Detection Logic

The system must define how reality drift is identified.

This may include:

- reality-model mismatches
- prediction failures
- environmental inconsistencies
- operational deviations
- evidence-model conflicts
- validation anomalies

4. Define Operational Response or Governance Logic

The system must define governance logic for reality-drift conditions.

Governance response may include:

- model review
- alignment reassessment
- adaptation activation
- governance intervention
- escalation
- model restriction
- operational invalidation where required

5. Preserve Traceability & Restrict Invalid Conditions

The system must preserve reconstructable traceability of:

- drift events
- divergence measurements
- validation activities
- governance actions
- corrective interventions
- resulting model states

A cognition environment must not remain drift-valid if materially significant divergence from reality cannot be detected, measured, or governed.

Use Case 1 — Autonomous Environmental Monitoring System

Scenario

An autonomous monitoring environment continuously maintains models describing changing environmental conditions and operational states.

Application

RDIM governs divergence detection, drift measurement, and governance responses when internal models begin deviating from observed reality.

Result

The environment gains stronger situational awareness, improved adaptation capability, and reduced exposure to unnoticed reality-model failures.

Use Case 2 — Strategic Forecasting Organization

Scenario

An organization relies on predictive models to guide investment, planning, and operational decisions.

Application

RDIM governs reality-drift detection when forecasts increasingly diverge from observed market and operational conditions.

Result

The organization gains stronger forecasting accountability, improved model reliability, and reduced exposure to strategic blind spots.

Canonical Closing Statement

Reality Drift Integrity Module (RDIM) defines the structural conditions under which divergence between internal reality models and observable reality remains detectable, measurable, traceable, governable, and operationally valid throughout cognition and reality-modeling processes.

Reality models cannot remain valid when divergence from reality becomes invisible. Reality drift therefore becomes a foundational integrity condition of governable reality modeling.
