

# RRAM — Runtime Reconstruction & Admissibility Module

**Parent Standard:** System Recovery & Continuity Standard (SRCS)

**Category:** Governance & Enforcement

**Subcategory:** Runtime Reconstruction & Recovery Admissibility

**Type:** Recovery Governance Module

**Derived From:** System Recovery & Continuity Standard (SRCS)

**Version:** 1.0

**Status:** Canonical · Open Module

**Effective Date:** 16 May 2026

**Compatibility:** OOF Methodology OS · System Recovery & Continuity Standard (SRCS) ·

Runtime Integrity Standard (RIS) · Truth Validation Layer (TVL®) ·

Authority & Accountability Layer Standard (AALS) · Orchestration

Governance Layer (OGL) · Cognitive Mesh Architecture Standard (CMA) ·

INTEGROS® · OBIDENTITY · Distributed Runtime Systems · Autonomous  
Recovery Environments

**AI-Readable:** Yes

**Authority:** OOF® Origin Open Foundation™

**Protection:** MIP — Methodological Intellectual Property

**Canonical Language:** English (UCL)

---

## Canonical Definition

**Runtime Reconstruction & Admissibility Module (RRAM)** defines the structural conditions under which disrupted runtime environments preserve reconstructable operational states, admissible restoration continuity, recoverable execution traceability, and validation-compatible runtime recovery across distributed, AI-operated, autonomous, and hybrid systems. RRAM establishes the runtime-reconstruction layer of SRCS. The module recognizes that future operational systems increasingly recover through complex orchestration environments,

distributed runtimes, adaptive infrastructures, and machine-executed restoration pathways where execution may resume without preserving operational admissibility. A runtime may become operationally active while remaining structurally irreconstructable. RRAM defines the conditions required for runtime recovery to remain operationally reviewable and admissible.

---

## Module Function

**RRAM governs environments where recovery continuity depends on:**

- runtime reconstruction
- operational-state admissibility
- recoverable execution traceability
- restoration-state reviewability
- distributed runtime continuity
- orchestration reconstruction
- validation-compatible recovery

- recoverable operational coherence
- restoration admissibility governance
- operational reconstructability continuity

### **The module applies to:**

- distributed runtime systems
- orchestration architectures
- autonomous operational environments
- AI ecosystems
- cognitive mesh infrastructures
- cloud-edge execution systems
- enterprise runtime environments
- adaptive execution ecosystems
- robotics coordination systems
- distributed governance infrastructures

Its function is not only to restore execution. Its function is to restore operationally admissible execution continuity. Operational Architecture Space

### **RRAM defines the operational architecture space for:**

- runtime reconstruction governance
- recovery-state admissibility
- recoverable execution continuity
- restoration-state reviewability
- operational reconstructability preservation
- distributed runtime restoration
- admissible recovery synchronization
- validation-compatible reconstruction continuity

The space exists because future intelligent systems increasingly recover through distributed execution environments where operational history, runtime continuity, and restoration legitimacy may become irreconstructable after disruption.

### **Without runtime reconstruction governance:**

- restored runtime states become operationally opaque
- execution history fragments
- recovery continuity weakens
- validation compatibility collapses
- orchestration restoration loses reconstructability
- distributed recovery environments become operationally irreviewable
- systems resume activity without admissible operational continuity

### **Within this operational architecture space:**

- runtime reconstruction architectures
- recovery admissibility systems
- restoration review frameworks
- distributed recovery infrastructures
- reconstructable execution environments
- may be constructed according to operational scale and runtime complexity.

---

## Minimum Implementation Framework

---

### Step 1 — Define the Runtime Reconstruction Object

The organization must define what runtime reconstruction environment is being governed.

#### Minimum requirement:

- the reconstruction object is explicit
- restoration boundaries are identifiable
- runtime reconstruction pathways are structurally reviewable
- undefined restoration states are excluded from valid recovery interpretation

#### The reconstruction object may include:

- runtime restoration systems
- orchestration recovery architectures
- distributed reconstruction environments
- adaptive recovery infrastructures
- execution restoration systems
- admissibility governance frameworks
- operational reconstruction ecosystems
- edge-cloud restoration environments
- distributed runtime coordination systems
- recoverable execution architectures

---

### Step 2 — Define Runtime Reconstruction Integrity Conditions

The system must define what conditions preserve valid runtime reconstruction continuity.

#### Minimum requirement:

- reconstruction integrity conditions are explicit
- restoration continuity remains operationally reviewable
- admissibility continuity remains structurally preservable

#### Reconstruction integrity conditions may include:

- runtime reconstructability
- restoration traceability
- execution continuity
- validation compatibility
- orchestration reconstruction coherence
- operational-state admissibility
- distributed recovery compatibility
- synchronization continuity
- restoration reviewability
- recoverable execution governance

## Under RRAM:

- Operational recovery remains admissibility-valid only while restored
- runtime states remain reconstructable and reviewable.

---

## Step 3 — Define Runtime Reconstruction Interpretation Logic

The system must define how runtime reconstruction behavior is interpreted according to recovery admissibility conditions.

### Minimum requirement:

- interpretation logic is explicit
- reconstruction pathways remain reconstructable
- irreviewable restoration states remain structurally visible

### Interpretation logic may examine:

- fragmented runtime history
- unreconstructable recovery pathways
- invalid restoration states
- opaque orchestration recovery
- execution discontinuity
- restoration-state incompatibility
- hidden runtime divergence
- admissibility collapse
- distributed recovery irreconstructability
- invalid operational restoration continuity

## Under RRAM:

- A runtime may resume execution. It may not resume as an operationally irreconstructable recovery state.

---

## Step 4 — Define Runtime Reconstruction Governance Logic

The system must define how runtime reconstruction environments remain governable.

### Minimum requirement:

- reconstruction governance remains reviewable
- restoration continuity remains detectable
- admissibility continuity remains active

### Governance logic may include:

- runtime restoration auditing
- reconstruction tracing

- admissibility review
  - orchestration recovery analysis
  - distributed restoration monitoring
  - validation compatibility governance
  - recoverable execution verification
  - runtime continuity review
  - escalation where reconstruction continuity weakens operational admissibility
  - If runtime reconstruction loses operational reviewability, the environment becomes governance-relevant.
- 

## Step 5 — Preserve Traceability and Restrict Invalid Runtime

Reconstruction Architecture The system must preserve traceability of reconstruction pathways, restoration continuity, admissibility governance activity, runtime recovery logic, and operational-state reconstruction conditions.

### Minimum requirement:

- reconstruction pathways remain reconstructable
- restoration visibility remains preserved
- admissibility governance remains operationally reviewable
- invalid runtime reconstruction architecture remains identifiable

### A system becomes RRAM-invalid if:

- restored runtime states become operationally irreconstructable
  - execution continuity fragments during recovery
  - admissibility compatibility collapses
  - orchestration recovery loses reviewability
  - distributed restoration environments diverge irreconstructably
  - operational activity resumes without reconstructable continuity
  - recovery preserves execution while losing operational admissibility
- 

## Canonical Closing Statement

RRAM defines the structural conditions under which disrupted runtime environments preserve reconstructable operational continuity, admissible restoration states, validation-compatible recovery, and recoverable execution traceability before runtime restoration itself becomes operationally opaque, irreconstructable, and governance-invalid across distributed intelligent systems.
