

SRVM — Structured Reality Validation Module

Parent Standard: Structured Reality Standard

Category: Governance & Enforcement

Subcategory: Structured Reality Validation

Type: Reality Validation Architecture Module

Version: 1.0

Status: Canonical · Open Module

Effective Date: 13 May 2026

Compatibility: OOF Methodology OS · Structured Reality Standard · MTVF · INTEGROS · Runtime Integrity Standard · UCL · ORGS

Authority: OOF

Protection: MIP — Methodological Intellectual Property

Canonical Language: English

Canonical Definition

Structured Reality Validation Module defines the structural conditions under which a declared reality state, claim, output, system condition, or evidence-backed representation may be evaluated for structural validity before being treated as methodologically fit for later truth validation, integrity enforcement, runtime governance, or trust attribution.

A system satisfies SRVM only if:

- the declared reality object is explicitly defined
- the supporting structure of that reality claim is identifiable
- meaning remains stable enough for structural evaluation
- origin and evidence continuity remain reviewable
- the validation path can distinguish grounded structure from formal appearance
- structural validity is determined before later layers assume the claim is fit for deeper validation

A system that validates claims without first testing whether the reality claim itself is structurally formed does not satisfy SRVM.

Module Function

SRVM defines the validation entry layer of structured reality governance.

It ensures that systems do not move directly from claim to acceptance, from output to assumed validity, or from documentation to structural recognition without first testing whether the claimed reality is built on sufficiently defined methodological ground.

The module applies wherever a system must examine whether a declared reality condition is structurally fit to proceed into:

- truth validation

- integrity enforcement
- runtime governance
- audit review
- trust architecture
- compliance interpretation
- decision support
- cross-system compatibility assessment

Its function is not to prove final truth.

Its function is to determine whether the reality claim is structured well enough to deserve validation at all.

Step 1 — Define the Reality Validation Object

The organization must define what exactly is being evaluated for structured reality validity.

Minimum requirement:

- the validation object is explicit
- the object of reality evaluation is structurally bounded
- undefined or shifting validation targets are excluded from valid SRVM logic

The validation object may be a:

- claim
 - declared state
 - output
 - decision condition
 - evidence-backed statement
 - operational representation
 - compliance assertion
 - system-reported reality condition
-

Step 2 — Define the Claimed Reality Structure

The system must define what structural components support the declared reality claim.

Minimum requirement:

- the supporting structure is explicit
- the claim is not treated as self-validating
- reality validation does not begin from wording alone

The supporting structure may include:

- claim definition
 - semantic framing
 - origin chain
-

- evidence links
- state conditions
- structural dependencies
- validation pathway
- distortion boundaries

Without declared structure, reality validation becomes procedural theater rather than structural examination.

Step 3 — Define Meaning Stability Conditions

The system must define how the key terms and claimed meanings remain stable during validation.

Minimum requirement:

- meaning conditions are explicit
- semantic drift is restricted
- the same claim is not allowed to change meaning while being validated

This means the system must remain able to determine:

- what the claim means
- whether the meaning remains stable
- whether the meaning changed during validation
- whether reality structure and declared meaning still align

If meaning is unstable, structural validation becomes unreliable before truth evaluation even begins.

Step 4 — Define Origin and Evidence Continuity

The system must define how origin continuity and evidence continuity support the reality claim.

Minimum requirement:

- origin continuity is reviewable
- evidence continuity is reconstructable
- structural validation does not proceed on detached or selectively arranged support alone

This includes determining:

- where the claim came from
- what evidence supports it
- whether the evidence chain remains intact
- whether origin and evidence remain aligned with the declared reality structure

Without origin and evidence continuity, structural validation

collapses into surface assessment.

Step 5 — Define Structural Validity Logic

The system must define how structural validity is determined.

Minimum requirement:

- structural validity logic is explicit
- the system can distinguish valid structure from vague appearance
- a claim does not pass merely because process occurred around it

This means the system must remain able to determine whether:

- the reality claim is sufficiently defined
- the structure beneath it is coherent
- the evidence chain is materially connected
- the meaning remains stable
- distortion has been structurally excluded enough for further validation to proceed

Step 6 — Preserve Validation Traceability

The system must preserve traceability of the structural reality validation process itself.

Minimum requirement:

- validation decisions are reviewable
- the structural basis of acceptance or rejection remains reconstructable
- later audit can determine why a claim was considered structurally fit or structurally invalid

If structured reality validation cannot be reconstructed, later trust in the validation path weakens immediately.

Step 7 — Restrict Invalid Structural Validation

The system must not be treated as valid if it validates declared reality through formal sequence alone while structural weakness remains unresolved.

Minimum requirement:

- invalid structural validation conditions are identifiable
- procedural passage is excluded as sufficient proof of structural reality
- claims lacking defined structure, stable meaning, origin continuity, or evidence continuity are blocked, bounded, or
- invalidated before later validation layers rely on them

Scenario

An organization declares that a product, process, or operational state is compliant and valid because it passed formal review and documentation procedures.

Application

SRVM is used to ensure:

- the compliance claim itself is structurally defined
 - the supporting reality structure is explicit
 - meaning remains stable across the declared claim
 - origin and evidence continuity are strong enough for validation to proceed
 - apparent compliance is not mistaken for structured reality validity
-

Result

The organization gains a stronger validation architecture in which declared compliance is tested as structured reality rather than accepted as process output alone.

Scenario

An AI system generates a classification, decision support output, or summary that represents a claimed reality condition.

Application

SRVM is used to ensure:

- the claimed reality object is explicitly bounded
 - the structural basis of the claim is identifiable
 - meaning remains stable enough for evaluation
 - evidence and origin continuity can support the output structurally
 - the system does not mistake coherent output for structurally valid reality representation
-

Result

The environment gains a stronger reality-validation architecture in which AI-generated claims are structurally screened before deeper truth, trust, or governance layers depend on them.

Canonical Closing Statement

If a claimed reality is not structurally fit for validation, later validation only deepens the appearance of order without grounding the claim itself.
