

TVL® Truth Validation Standard

OOF™ Origin Open Foundation™

Independent Methodological Authority

STANDARD TITLE:

Truth Validation Standard

OriginID: OOF-OID-AI-INT-TV-2026-03-15-0001

Category: AI Interpretation Standards (AI)

Subcategory: Truth Validation

Version: 1.1

Status: Canonical · Open Standard

Effective Date: 15 March 2026

Compatibility:

MTVF™ · AI Governance Frameworks · ArtData™ · OOF Methodology OS™

Authority: OOF™ Origin Open Foundation™

Protection: MIP™ — Methodological Intellectual Property

Canonical Language: English (UCL™)

A. Standard Abstract

The **Truth Validation Standard** establishes a structural framework for verifying the reliability of information used in automated decision environments, including artificial intelligence systems.

The standard defines the minimum conditions under which statements, datasets, or decision outputs may be considered structurally validated.

Truth Validation does not define truth as opinion, authority, or isolated technical output. Instead, it establishes a methodological process in which truth emerges from structured validation across independent layers of verification.

This standard provides the conceptual and methodological foundation for systems that require reliable information validation, including AI decision environments, governance systems, and high-risk automated processes.

B. Canonical Definition

Truth Validation is a structured methodological process through which information, claims, or decision outputs are verified across independent validation layers in order to establish reliability, traceability, and contextual integrity.

Truth is defined as the result of a **validated multi-layer process** rather than the assertion of a single source.

Truth Validation ensures that information used in automated or human decision systems

is empirically grounded, contextually evaluated, and structurally auditable.

C. Structural Principle

The Truth Validation Standard is based on the principle that **single-source verification is insufficient** for high-impact decisions. Reliable validation requires structural separation between validation layers in order to prevent bias propagation and systemic error. Within this standard, validation may include:

- empirical verification of measurable inputs
- cross-source consistency evaluation
- contextual interpretation within governance frameworks
- integrity checks across validation layers

The objective is not to eliminate disagreement but to ensure that decision-relevant information passes through structured verification conditions.

D. Source Traceability Principle

Truth Validation requires that information used within validation processes originates from **traceable and accountable sources**. Inputs lacking identifiable origin, responsibility declaration, or traceable provenance cannot be considered empirically valid within this methodology. Traceability ensures that validation processes remain resistant to:

- synthetic data contamination
- unverifiable information sources
- recursive AI-generated input loops
- anonymous or manipulated data streams

Where applicable, traceable dataset structures such as those defined in **ArtData™** may be used to establish verifiable data provenance within validation processes.

E. Scope

The Truth Validation Standard may be applied to environments where reliable information validation is critical, including:

- artificial intelligence decision systems
- automated financial analysis
- medical decision support systems
- governance and regulatory evaluation
- high-risk algorithmic decision processes

The standard does not replace regulatory authorities or certification bodies. Instead, it establishes **methodological infrastructure** for structured validation of information used in decision systems.

Structural Position within the Validation Architecture

The Truth Validation Standard provides the conceptual foundation for operational validation systems such as the **Multi-Layer Truth Validation Framework (MTVF™)**. Within the OOF methodology architecture:

Truth Validation Standard

This structure enables validation processes to move from conceptual verification toward operational integrity control.

Canonical Closing Statement

Reliable decisions require reliable validation.

Truth Validation establishes the structural conditions under which information can be evaluated with integrity within complex decision environments.
