

VALIDOS® Validation Governance Architecture — Validation Governance Layer

Validation Governance Architecture — Validation Governance Layer

Official Validation Governance Architecture for AI Systems, Autonomous Systems,

Digital Assets, Organizations, Critical Infrastructure, Decision Systems, Scientific

Claims, Operational Processes, and Future Validation Environments

VALIDOS® serves as the official OOF® validation governance architecture used for validation object definition, validation scope governance, validation criteria design, validation method governance, evidence fitness assessment, source reliability assessment, validation execution, validation determination, validation state governance, validation reliance, and revalidation across AI systems, autonomous systems, organizations, digital assets, critical infrastructure, decision environments, scientific and technical systems, and future operational ecosystems.

VALIDOS® does not determine what must be considered true, safe, compliant, reliable, or acceptable in every domain. VALIDOS® defines the governance architecture required to ensure that validation remains structurally defined, evidentially grounded, methodologically controlled, operationally executed, formally determined, lifecycle-governed, reliance-bounded, and continuously revalidatable.

VALIDOS® consists of 10 Core Parent Standards forming the primary validation governance backbone within the OOF® ecosystem.

Additional compatible standards, specialized validation frameworks, validation protocols, bridge standards, and domain-specific validation systems may extend the architecture when new validation governance spaces are identified. However, the standards listed below form the official core governance structure of VALIDOS®.

Canonical Definition

VALIDOS® — Validation Governance Architecture is the validation governance architecture that defines the structural conditions under

which Validation Objects can be identified, scoped, evaluated against governed criteria, examined through appropriate methods, supported by fit evidence and reliable sources, operationally validated, formally determined, assigned governable Validation States, legitimately relied upon, and revalidated throughout their complete lifecycle.

Core Question

How can validation remain structurally defined, evidentially grounded, methodologically controlled, operationally valid, reliance-bounded, and continuously governable throughout the complete lifecycle of a Validation Object?

Governance Flow

Validation Object → Validation Purpose & Scope → Validation Criteria
→ Validation Method → Validation Evidence Fitness → Validation
Source Reliability → Validation Execution → Validation Determination
→ Validation State → Validation Reliance & Revalidation

Core Parent Standards

1. Validation Object Standard (VOS)

Governed Space: Validation Object

Core Question: What exactly is being validated, how is the Validation Object uniquely bounded and identified, and how can its identity remain stable throughout the validation lifecycle?

2. Validation Purpose & Scope Standard (VPSS)

Governed Space: Validation Purpose & Scope

Core Question: Why is validation being performed, what must it cover, what remains outside its boundaries, and at what Validation Depth must the inquiry operate?

3. Validation Criteria Standard (VCS)

Governed Space: Validation Criteria

Core Question: Against which explicit, applicable, sufficient, and governed criteria must the Validation Object be evaluated?

4. Validation Method Standard (VMS)

Governed Space: Validation Method

Core Question: Which validation method is appropriate for the Validation Object, purpose, scope, criteria, consequence, and required Validation Depth?

5. Validation Evidence Fitness Standard (VEFS)

Governed Space: Validation Evidence Fitness

Core Question: Is the available evidence sufficiently relevant, complete, current, representative, usable, and fit to support the intended validation determination?

6. Validation Source Reliability Standard (VSRS)

Governed Space: Validation Source Reliability

Core Question: Are the sources producing or supporting validation evidence sufficiently identifiable, capable, reliable, independent where necessary, and traceable for the intended validation purpose?

7. Validation Execution Standard (VES) Governed Space:

Validation Execution

Core Question: How must an approved validation method be operationally executed, controlled, observed, documented, and audited so that the resulting validation record remains trustworthy?

8. Validation Determination Standard (VDS)

Governed Space: Validation Determination

Core Question: What conclusion does the complete governed validation record legitimately support, and how must uncertainty, conflict, negative findings, conditions, and partial outcomes remain reflected in that determination?

9. Validation State Governance Standard (VSGS)

Governed Space: Validation State Governance

Core Question: What Validation State does the Validation Object legitimately hold now, where and under which conditions does that state apply, and how must the state change when validation-relevant reality changes?

10. Validation Reliance & Revalidation Standard (VRRS)

Governed Space: Validation Reliance & Revalidation

Core Question: Who or what may legitimately rely upon the current Validation State, for which purpose and scope, under which conditions and level of consequence, for how long, and when must that reliance be reconsidered through revalidation?

VALIDOS® Four-Layer Validation Protocol™

VALIDOS® may be operationalized through the VALIDOS® — Four-Layer Validation Protocol™ (4LVP™).

The protocol compresses the broader validation architecture into four mandatory operational validation layers:

Layer 1 — Object & Scope Validation

Layer 2 — Evidence & Source Validation

Layer 3 — Execution & Determination Validation

Layer 4 — State & Reliance Validation

The protocol does not replace the 10 Core Parent Standards.

VALIDOS® defines the validation governance architecture. 4LVP™ defines a compact operational pathway through that architecture.

Its core conformity principle is:

No validation claim may exceed the weakest unresolved validation layer on which that claim materially depends.

Compatible OOF® Architectures

VALIDOS® interoperates with multiple OOF® architectures governing complementary methodological and operational spaces.

GOA™ — Governance Architecture provides the constitutional governance layer defining authority, boundaries, scope, delegation, accountability, validation, transparency, integrity, continuity, and interoperability of governance itself.

ORA™ — Operational Reality Architecture governs whether validation assumptions, execution conditions, and resulting states remain representative of actual operational reality.

OBIDENTITY® — Identity Governance Architecture governs origin, identity, ownership, authority, provenance, transfer, and continuity of Validation Objects, evidence sources, actors, and governed records.

INTEGROS® — Integrity Governance Architecture provides complementary integrity governance for evidence, validation records, execution artifacts, determinations, state information, and lifecycle continuity.

AGA™ — Accountability Governance Architecture governs responsibility for validation design, execution, determination, reliance authorization, revalidation initiation, and downstream decisions.

CLIA® — Cognitive Governance Intelligence Architecture governs cognition, reasoning, interpretation, and cognitive integrity where human or machine interpretation materially influences validation.

MGIA™ — Memory Governance Intelligence Architecture governs memory, historical continuity, retained validation records, lifecycle reconstruction, and the persistence or correction of validation-relevant information.

AIG® — AI Governance Architecture governs behavioral conditions of AI systems where AI behavior forms part of the Validation Object, validation method, operational execution, or reliance context.

ASGA™ — Autonomous Systems Governance Architecture governs autonomous authority, permissions, constraints, escalation, operational control, and lifecycle conditions where autonomy materially affects validation.

RIS™ provides complementary risk and consequence information capable of affecting Validation Depth, validation urgency, monitoring intensity, reliance restrictions, and revalidation requirements.

SIMULOS® may provide governed simulation environments and simulation-derived evidence used within validation where simulation itself remains sufficiently controlled and valid.

VALIDOS® serves as the common validation governance architecture supporting the broader OOF® ecosystem by ensuring that validation claims remain bounded by the objects, evidence, sources, methods, execution records, determinations, states, and reliance conditions that legitimately support them.

Architectural Position

VALIDOS® governs the complete validation governance lifecycle.

The architecture progresses through:

**Validation Object → Validation Purpose & Scope → Validation Criteria
→ Validation Method → Validation Evidence Fitness → Validation
Source Reliability → Validation Execution → Validation Determination
→ Validation State → Validation Reliance & Revalidation**

Together these standards govern how a Validation Object is

identified, why and where it is validated, against what requirements it is examined, how validation is methodologically performed, what evidence and sources may legitimately support it, how execution is controlled, what determination may be drawn, what Validation State results, how that state may be relied upon, and how material change returns the object into revalidation.

VALIDOS® therefore begins as a governed sequence but becomes a **recursive validation lifecycle** once operational reliance begins.

The extended lifecycle becomes:

Validation Object

- **Purpose & Scope**
- **Criteria**
- **Method**
- **Evidence**
- **Sources**
- **Execution**
- **Determination** → **Validation State**
- **Reliance**
- **Monitoring**
- **Material Change**
- **Revalidation Trigger**
- **Validation Delta**
- **Lifecycle Re-Entry**
- **New Validation Determination**
- **New Validation State**
- **Renewed, Restricted, Suspended, or Withdrawn Reliance**

This cycle may continue for the complete operational lifetime of the Validation Object.

Canonical Principle

VALIDOS® does not declare an object valid merely because validation activity occurred. VALIDOS® governs the structural conditions under

which a validation claim may legitimately exist, remain bounded by its actual evidential and methodological basis, support operational reliance, and return to revalidation whenever the reality supporting that claim materially changes.

Cross-Architecture Interfaces

→ GOA™ — Governance Architecture

Direction: Bidirectional governance interface

Governed boundary: GOA governs governance architecture and constitutional conditions; VALIDOS governs the lifecycle through which Validation Objects acquire, maintain, change, or lose governed validation status.

→ ORA™ — Operational Reality Architecture

Direction: Operational Reality to validation governance, with governed feedback

Governed boundary: ORA governs what is occurring in Operational Reality; VALIDOS governs whether a defined Validation Object can support a validation determination under governed conditions.

→ OBIDENTITY® — Origin-Bound Identity Governance Architecture

Direction: Identity and provenance into validation governance

Governed boundary: OBIDENTITY governs origin, identity, ownership, authority, permission, provenance, transfer, and continuity; VALIDOS governs their validation-specific use.

→ INTEGROS® — Integrity Governance Architecture

Direction: Integrity conditions into validation determination and reliance

Governed boundary: INTEGROS governs integrity across objects, information, states, processes, and records; VALIDOS governs whether the complete validation basis supports determination, state, and bounded reliance.

→ ADIT® — Continuous Audit & Evidence Governance Architecture

Direction: Evidence governance into the validation lifecycle

Governed boundary: ADIT governs evidential observation, preservation, verification, traceability, and auditability; VALIDOS governs evidence fitness and use within validation.

→ AGA™ — Accountability Governance Architecture

Direction: Accountability governance around validation activity

Governed boundary: AGA governs authority, responsibility, accountability, attribution, escalation, and decision relationships; VALIDOS governs validation methodology, execution, determination, state, reliance, and revalidation.
