

Validation Object Boundary Module (VOBM)

Architecture Ecosystem: Structured Reality Standards™

Architecture Family: VALIDOS® — Validation Governance Architecture

Parent Standard: Validation Object Standard (VOBS)

Operational Layer: Validation Object Governance Layer

Category: AI & Interpretation

Subcategory: Validation Governance

Type: Parent Standard Module

Governed Space: Validation Object Boundary

Version: 1.0

Status: Canonical · Open Module

Effective Date: 7 August 2026

Compatibility: OOF® Methodology OS™ · GOA™ · OBIDENITY® · INTEGROS®
· ORA™ · AGA™ · AIG® · CLIA® · MGIA™ · ASGA™ · RIS™

AI-Readable: Yes

Authority: OOF®

Protection: MIP® — Methodological Intellectual Property

Canonical Language: English (UCL™)

Governed Space

Validation Object Boundary

Canonical Definition

Validation Object Boundary Module (VOBM) defines the governance framework for establishing, distinguishing, maintaining, and documenting the boundaries of a Validation Object.

It establishes the conditions necessary to determine which structural, informational, operational, temporal, contextual, and dependency-related elements belong within the Validation Object and which elements remain outside the object for the purposes of governed validation.

Operational Role

VOBM governs the boundary layer of Validation Object governance.

Its role is to ensure that the object being validated has an explicit and governable perimeter so that validation conclusions cannot be unintentionally extended to components, states, environments, periods, relationships, or conditions that were not included within the validated object.

Module Operational Space

VOBM governs:

- Validation Object boundaries,
 - inclusion conditions,
 - exclusion conditions,
 - structural boundaries,
 - informational boundaries,
 - operational boundaries,
 - temporal boundaries,
 - contextual boundaries,
 - dependency boundaries,
 - boundary ambiguity,
 - boundary change,
 - and boundary traceability.
-

Module Function

VOBM applies wherever the validity of a validation determination depends on knowing precisely what was included within or excluded from the Validation Object.

Its function is to prevent:

- undefined validation boundaries,
 - uncontrolled expansion of validation scope,
 - incorrect inclusion of external components,
 - omission of materially relevant components,
 - validation conclusions being extended beyond the object examined,
 - ambiguity between the Validation Object and its environment,
 - and loss of boundary continuity during the validation lifecycle.
-

Minimum Implementation Framework

1. Identify Boundary Dimensions

Determine which boundary dimensions are relevant to the Validation Object, including where applicable:

- structural,
 - informational,
 - operational,
 - temporal,
 - contextual,
 - organizational,
 - environmental,
 - and dependency-related boundaries.
-

2. Define Inclusion Conditions

Establish which components, states, information, operations, periods, relationships, or environments belong within the Validation Object.

3. Define Exclusion Conditions

Establish which elements remain outside the Validation Object and therefore are not directly covered by validation conclusions applying to that object.

4. Assess Boundary Dependencies

Determine whether external components or conditions outside the formal object boundary can materially influence the validity of the object or the interpretation of validation results.

Where such dependencies exist, they must remain visible to subsequent validation governance.

5. Preserve Boundary Records

Maintain:

- boundary definitions,
- inclusion records,
- exclusion records,
- boundary assumptions,
- dependency references,
- boundary changes,
- boundary decisions,
- timestamps,
- and sufficient governance traceability to reconstruct the boundary applicable at the time of validation.

Use Case 1 — AI System Validation

Scenario

An organization validates an AI application consisting of a foundation model, retrieval system, proprietary dataset, orchestration layer, and external APIs.

Application

VOBM establishes which components form part of the Validation Object and which external services remain outside its formal boundary while still being recorded as material dependencies.

Result

The resulting validation determination cannot be incorrectly interpreted as covering systems, services, or dependencies that were

not actually included within the validated object.

Use Case 2 — Operational Process Validation

Scenario

An organization validates a business process operating across several departments and external service providers.

Application

VOBM establishes the operational beginning and end of the Validation Object, identifies included process stages, records excluded activities, and preserves relevant external dependencies.

Result

The validation determination remains limited to the exact operational process that was examined and does not create unsupported assurance beyond its established boundary.

Canonical Closing Statement

Validation Object Boundary Module establishes the canonical governance framework for defining the perimeter of a Validation Object. By governing inclusion, exclusion, structural, informational, operational, temporal, contextual, and dependency boundaries, VOBM ensures that validation determinations remain constrained to the exact object actually examined and cannot be extended beyond their governed applicability.
